

# High Availability (SSO) Deployment Guide

Last Updated: February 25, 2021

**Note:** The documentation set for this product strives to use bias-free language. For purposes of this documentation set, bias-free is defined as language that does not imply discrimination based on age, disability, gender, racial identity, ethnic identity, sexual orientation, socioeconomic status, and intersectionality. Exceptions may be present in the documentation due to language that is hardcoded in the user interfaces of the product software, language used based on RFP documentation, or language that is used by a referenced third-party product.

## Introduction

This guide provides information on the theory of operation and configuration for the Cisco Unified Wireless LAN Controller (WLC) as it pertains to supporting stateful switchover of access points and clients (AP and Client SSO).

The new High Availability (HA) feature (that is, AP SSO) set within the Cisco Unified Wireless Network software release version 8.0 and above allows the access point (AP) to establish a CAPWAP tunnel with the Active WLC and share a mirror copy of the AP database with the Standby WLC. The APs do not go into the Discovery state when the Active WLC fails and the Standby WLC takes over the network as the Active WLC.

There is only one CAPWAP tunnel maintained at a time between the APs and the WLC that is in an Active state. The overall goal for the addition of AP SSO support to the Cisco Unified Wireless LAN is to reduce major downtime in wireless networks due to failure conditions that may occur due to box failover or network failover.

To support High Availability without impacting service, there needs to be support for seamless transition of clients and APs from the active controller to the standby controller. Release 7.5 supports Client Stateful Switch Over (Client SSO) in Wireless LAN controllers. Client SSO will be supported for clients which have already completed the authentication and DHCP phase and have started passing traffic. With Client SSO, a client's information is synced to the Standby WLC when the client associates to the WLC or the client's parameters change. Fully authenticated clients, i.e. the ones in Run state, are synced to the Standby and thus, client re-association is avoided on switchover making the failover seamless for the APs as well as for the clients, resulting in zero client service downtime and no SSID outage.

## WLC and Supported APs in rel 8.7

The information in this document is based on these software and hardware versions:

- WLCs 3500 Series, 8500 Series and 5520.
- Legacy Wave-1 APs: 3700, 2700, 1700, 702, 702W, 1530, 1570
- Wave-2 APs: 1800 series, 2800 series, 3800 series, 1540, 1560
- The information in this document was created from the devices in a specific lab environment. All of the devices used in this document started with a cleared (default) configuration. If your network is live, make sure that you understand the potential impact of any command.

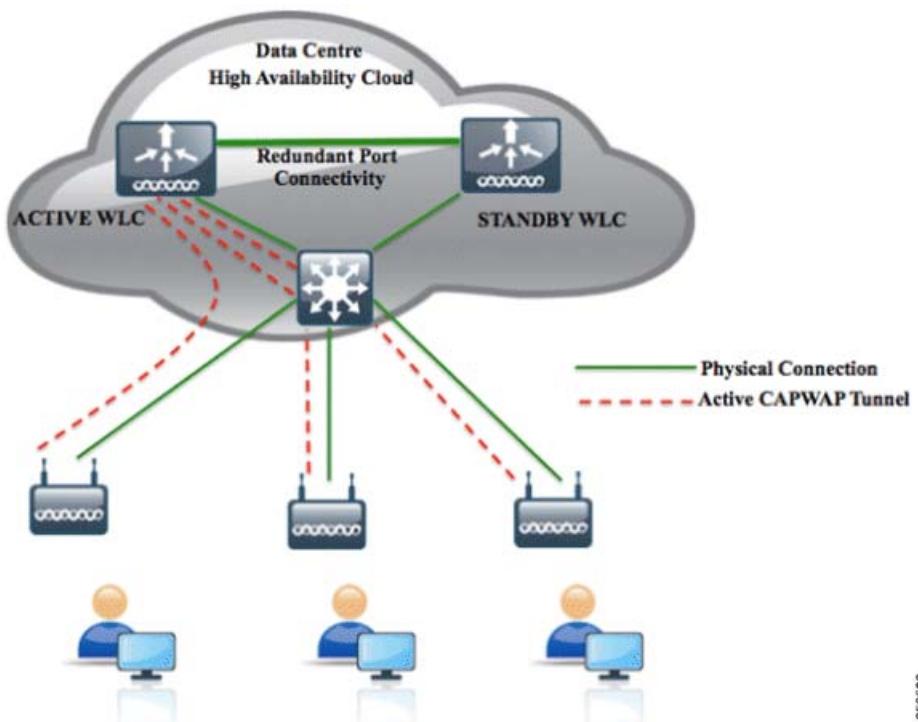

**Note:** 5508, 7500, 8510 and WiSM-2 are supported up to release 8.5. 3504 series is supported starting with release 8.5. See release notes for complete details.

## Conventions

Refer to Cisco Technical Tips Conventions for more information on document conventions.

## Topology

This document uses this network topology.

350596

## Product or Feature Overview

The new architecture for HA is for box-to-box redundancy. In other words, 1:1 where one WLC will be in an Active state and the second WLC will be in a Hot Standby state continuously monitoring the health of the Active WLC via a Redundant Port. Both the WLCs will share the same set of configurations including the IP address of the Management interface. The WLC in the Standby state does not need to be configured independently as the entire configuration (Bulk Configuration while boot up and Incremental Configuration in runtime) will be synced from the Active WLC to the Standby WLC via a Redundant Port. The AP's CAPWAP State (only APs which are in a run state) is also synced, and a mirror copy of the AP database is maintained on the Standby WLC. The APs do not go into the Discovery state when the Active WLC fails and the Standby WLC takes over the network's Active WLC. There is no preempt functionality. When the previous Active WLC comes back, it will not take the role of the Active WLC, but will negotiate its state with the current Active WLC and transition to a Standby state. The Active and Standby decision is not an automated election process. The Active/Standby WLC is decided based on HA SKU (Manufacturing Ordered UDI) from release 7.3 onwards. A WLC with HA SKU UDI will always be the Standby WLC for the first time when it boots and pairs up with a WLC running a permanent count license. For existing WLCs having a permanent count license, the Active/Standby decision can be made based on manual configuration.

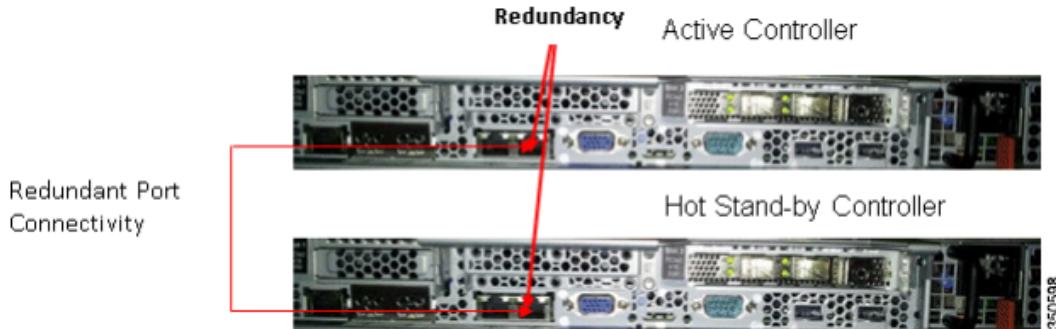

AP SSO is supported on 5500/7500/8500 and WiSM-2 WLCs. Release 7.3 only supports AP SSO that will ensure that the AP sessions are intact after switchover.

Client SSO is supported on 5500/7500/8500 and WiSM2 WLCs from release 7.5 onwards.

Client SSO is supported on 5520/3500/8500 WLCs from release 8.5 onwards.

## HA Connectivity Using Redundant Port on the 3504/5520/8500.

WLC 3500/5520/8500 WLCs have a dedicated Redundancy Port which should be connected back to back in order to synchronize the configuration from the Active to the Standby WLC.

Like 5520 and 8540, the 3504 Wireless Controller has a Redundancy port on the front of the unit. Like on other WLC, WLC 3504 supports both AP SSO and Client SSO. Given below is how one would connect two WLC 3504 using the RP port (back to Back) in HA Setup.

Keep-alive packets are sent on the Redundancy Port from the Standby to the Active WLC every 100 msec (default timer) in order to check the health of the Active WLC.

Both the WLCs in HA setup keep track of gateway reachability. The Active WLC sends an Internet Control Message Protocol (ICMP) ping to the gateway using the Management IP address as the source, and the Standby WLC sends an ICMP ping to the gateway using the Redundancy Management IP address. Both the WLCs send an ICMP ping to the gateway at a one-second interval. It is highly recommended to have back-to-back direct connectivity between Redundant Ports.

**Note:** A direct physical connection between Active and Standby Redundant Ports is highly recommended. The distance between the connections can go up to 100 meters at per Ethernet cable standards.

## Introduction of New Interfaces for HA Interaction

### Redundancy Management Interface

The IP address on this interface should be configured in the same subnet as the management interface. This interface will check the health of the Active WLC via network infrastructure once the Active WLC does not respond to Keepalive messages on the Redundant Port. This provides an additional health check of the network and Active WLC, and confirms if switchover should or should not be executed. Also, the Standby WLC uses this interface in order to source ICMP ping packets to check gateway

## Product or Feature Overview

reachability. This interface is also used in order to send notifications from the Active WLC to the Standby WLC in the event of Box failure or Manual Reset. The Standby WLC will use this interface in order to communicate to Syslog, the NTP server, and the TFTP server for any configuration upload.

Interfaces					
	Interface Name	VLAN Identifier	IP Address	Interface Type	Dynamic AP Management
	<a href="#">management</a>	61	9.6.61.2	Static	Enabled
	<a href="#">redundancy-management</a>	61	9.6.61.21	Static	Not Supported
	<a href="#">redundancy-port</a>	N/A	169.254.61.21	Static	Not Supported

## Redundancy Port

This interface has a very important role in the new HA architecture. Bulk configuration during boot up and incremental configuration are synced from the Active WLC to the Standby WLC using the Redundant Port. WLCs in a HA setup will use this port to perform HA role negotiation. The Redundancy Port is also used in order to check peer reachability sending UDP keep-alive messages every 100 msec (default timer) from the Standby WLC to the Active WLC. Also, in the event of a box failure, the Active WLC will send notification to the Standby WLC via the Redundant Port. If the NTP server is not configured, a manual time sync is performed from the Active WLC to the Standby WLC on the Redundant Port. This port in case of standalone controller will be assigned an auto generated IP Address where last 2 octets are picked from the last 2 octets of Redundancy Management Interface (the first 2 octets are always 169.254).

**Note:** Redundancy Management Interface cannot be an Untagged Interface.

Interfaces					
	Interface Name	VLAN Identifier	IP Address	Interface Type	Dynamic AP Management
	<a href="#">management</a>	61	9.6.61.2	Static	Enabled
	<a href="#">redundancy-management</a>	61	9.6.61.21	Static	Not Supported
	<a href="#">redundancy-port</a>	N/A	169.254.61.21	Static	Not Supported

## Configure HA from the CLI

Complete these steps:

- Before you configure HA, it is mandatory to have both the controllers' management interface in the same subnet:

WLC 1:

```
(5508) >show interface summary

Number of Interfaces..... 5

Interface Name          Port Vlan Id   IP Address      Type    Ap Mgr Guest
-----                  --  --  --        --  --  --
management              1   61         9.6.61.2       Static  Yes  No
redundancy-management   1   61         0.0.0.0       Static  No   No
redundancy-port          N/A N/A        0.0.0.0       Static  No   No
service-port             N/A N/A        0.0.0.0       DHCP   No   No
virtual                 N/A N/A        1.1.1.1       Static  No   No
```

WLC 2:

## Product or Feature Overview

(5508) >show interface summary							
Number of Interfaces..... 5							
Interface Name	Port	Vlan Id	IP Address	Type	Ap Mgr	Guest	
management	1	61	9.6.61.3	Static	Yes	No	
redundancy-management	1	61	0.0.0.0	Static	No	No	
redundancy-port	N/A	N/A	0.0.0.0	Static	No	No	
service-port	N/A	N/A	0.0.0.0	DHCP	No	No	
virtual	N/A	N/A	1.1.1.1	Static	No	No	

2. HA is disabled by default. Before you enable HA, it is mandatory to configure the Redundancy Management IP Address and Peer Redundancy Management IP Address. Both the interfaces should be in the same subnet as the Management Interface. In this example, 9.6.61.21 is the Redundancy Management IP Address for WLC 1, and 9.6.61.23 is the Redundancy Management IP Address for WLC 2. It also needs to be configured so that 9.6.61.23 is the Redundancy Management IP Address of WLC 2 and 9.6.61.21 is the Redundancy Management IP Address of WLC 1.

Use this CLI in order to configure the Redundancy and Peer Redundancy Management IP Address:

WLC 1:

(5508) >config interface address redundancy-management 9.6.61.21 peer-redundancy-management 9.6.61.23							
(5508) >show interface summary							
Number of Interfaces..... 5							
Interface Name	Port	Vlan Id	IP Address	Type	Ap Mgr	Guest	
management	1	61	9.6.61.2	Static	Yes	No	
redundancy-management	1	61	9.6.61.21	Static	No	No	
redundancy-port	N/A	N/A	169.254.61.21	Static	No	No	
service-port	N/A	N/A	0.0.0.0	DHCP	No	No	
virtual	N/A	N/A	1.1.1.1	Static	No	No	

WLC 2:

(5508) >config interface address redundancy-management 9.6.61.23 peer-redundancy-management 9.6.61.21							
(5508) >show interface summary							
Number of Interfaces..... 5							
Interface Name	Port	Vlan Id	IP Address	Type	Ap Mgr	Guest	
management	1	61	9.6.61.2	Static	Yes	No	
redundancy-management	1	61	9.6.61.23	Static	No	No	
redundancy-port	N/A	N/A	169.254.61.23	Static	No	No	
service-port	N/A	N/A	0.0.0.0	DHCP	No	No	
virtual	N/A	N/A	1.1.1.1	Static	No	No	

3. Configure one WLC as Primary (by default, the WLC HA Unit ID is Primary and should have a valid AP-BASE count license installed) and another WLC as Secondary (AP base count from the Primary WLC will be inherited by this unit) using the CLI in this step. In this example, WLC 1 is configured as Primary, and WLC 2 is configured as Secondary:

WLC 1:

## Product or Feature Overview

```
(5508) >config redundancy unit primary
(5508) >show redundancy summary
Redundancy Mode = SSO DISABLED
  Local State = ACTIVE
  Peer State = N/A
    Unit = Primary
    Unit ID = 00:24:97:69:D2:20
Redundancy State = N/A
  Mobility MAC = 00:24:97:69:D2:20

  Redundancy Management IP Address..... 9.6.61.21
  Peer Redundancy Management IP Address..... 9.6.61.23
  Redundancy Port IP Address..... 169.254.61.21
  Peer Redundancy Port IP Address..... 169.254.61.23
```

WLC 2:

```
(5508) >config redundancy unit secondary
(5508) >show redundancy summary
Redundancy Mode = SSO DISABLED
  Local State = ACTIVE
  Peer State = N/A
    Unit = Secondary - HA SKU
    Unit ID = 00:24:97:69:78:20
Redundancy State = N/A
  Mobility MAC = 00:24:97:69:78:20

  Redundancy Management IP Address..... 9.6.61.23
  Peer Redundancy Management IP Address..... 9.6.61.21
  Redundancy Port IP Address..... 169.254.61.23
  Peer Redundancy Port IP Address..... 169.254.61.21
```

**Note:** You do not need to configure the unit as Secondary if it is a factory ordered HA SKU that can be ordered from release 7.3 onwards. A factory ordered HA SKU is a default Secondary unit, and will take the role of the Standby WLC the first time it is paired with an Active WLC that has a valid AP Count License.

If you want to convert any existing WLC as a Standby WLC, do so using the config redundancy unit secondary command in the CLI. This CLI command will only work if the WLC which is intended to work as Standby has some number of permanent license count. This condition is only valid for the 5508 WLC, where a minimum of 50 AP Permanent licenses are needed to be converted to Standby. There is no restriction for other WLCs such as the 5520, WiSM2, 7500, and 8500.

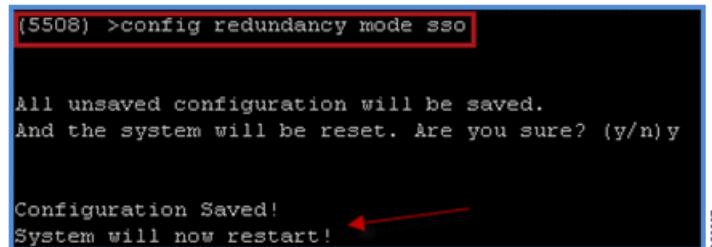

- After the WLCs are configured with Redundancy Management and Peer Redundancy Management IP Addresses and Redundant Units are configured, it is time to enable SSO. It is important to make sure that physical connections are up between both the controllers (that is, both the WLCs are connected back to back via the Redundant Port using an Ethernet cable) and the uplink is also connected to the infrastructure switch and the gateway is reachable from both the WLCs before SSO is enabled.

Once SSO is enabled, it will reboot the WLCs. While it boots, the WLCs negotiate the HA role as per the configuration via Redundant Port. If the WLCs cannot reach each other via Redundant Port or via the Redundant Management Interface, the WLC configured as Secondary may go into Maintenance Mode. Maintenance Mode is discussed later in this document.

- Use the CLI in this step in order to enable AP SSO. Remember that enabling AP SSO will initiate a WLC reboot.

WLC 1:

## Product or Feature Overview

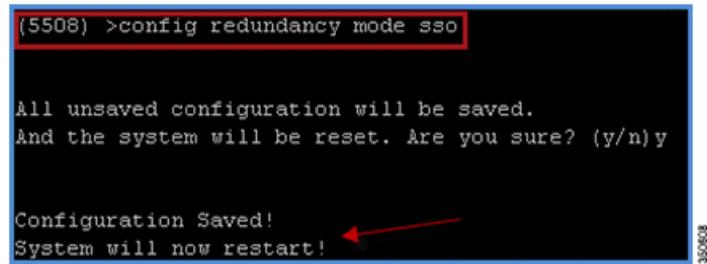

(5508) >config redundancy mode sso

All unsaved configuration will be saved.  
And the system will be reset. Are you sure? (y/n)y

Configuration Saved!  
System will now restart!

350807

WLC 2:

(5508) >config redundancy mode sso

All unsaved configuration will be saved.  
And the system will be reset. Are you sure? (y/n)y

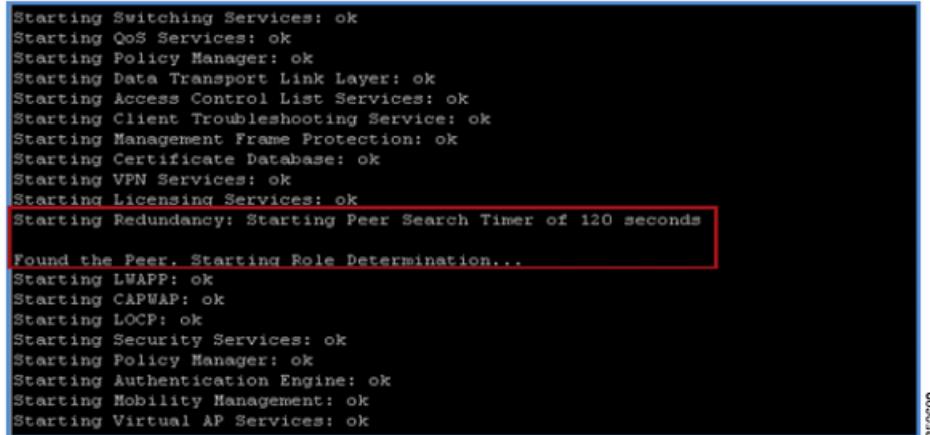

Configuration Saved!  
System will now restart!

350808

- Enabling SSO will reboot the WLCs in order to negotiate the HA role as per the configuration performed. Once the role is determined, configuration is synced from the Active WLC to the Standby WLC via the Redundant Port. Initially, the WLC configured as Secondary will report XML mismatch and will download the configuration from Active and reboot again. During the next reboot after role determination, it will validate the configuration again, report no XML mismatch, and process further in order to establish itself as the Standby WLC.

These are the boot-up logs from both the WLCs:

WLC 1:

```

Starting Switching Services: ok
Starting QoS Services: ok
Starting Policy Manager: ok
Starting Data Transport Link Layer: ok
Starting Access Control List Services: ok
Starting Client Troubleshooting Service: ok
Starting Management Frame Protection: ok
Starting Certificate Database: ok
Starting VPN Services: ok
Starting Licensing Services: ok
Starting Redundancy: Starting Peer Search Timer of 120 seconds
Found the Peer. Starting Role Determination...
Starting LWAPP: ok
Starting CAPWAP: ok
Starting LOCP: ok
Starting Security Services: ok
Starting Policy Manager: ok
Starting Authentication Engine: ok
Starting Mobility Management: ok
Starting Virtual AP Services: ok

```

350809

WLC 2 on first reboot after enabling SSO:

## Product or Feature Overview

```

Starting Client Troubleshooting Service: ok
Starting Management Frame Protection: ok
Starting Certificate Database: ok
Starting VPN Services: ok
Starting Licensing Services: ok
Starting Redundancy: Starting Peer Search Timer of 120 seconds

Found the Peer. Starting Role Determination...
Standby started downloading configurations from Active...

Standby comparing its own configurations with the configurations downloaded from Active...

Startup XMLs are different, reboot required
New XML downloaded Category: rsyncmgrXferTransport.
Restarting system ..
Restarting system.

350610

```

**Note:** Once SSO is enabled, the Standby WLC can be accessed via console connection or via SSH on the service port and on the redundant management interface.

WLC 2 on second reboot after downloading XML configuration from Active:

```

Starting Switching Services: ok
Starting QoS Services: ok
Starting Policy Manager: ok
Starting Data Transport Link Layer: ok
Starting Access Control List Services: ok
Starting System Interfaces: ok
Starting Client Troubleshooting Service: ok
Starting Management Frame Protection: ok
Starting Certificate Database: ok
Starting VPN Services: ok
Starting Licensing Services: ok
Starting Redundancy: Starting Peer Search Timer of 120 seconds

Found the Peer. Starting Role Determination...
Standby started downloading configurations from Active...

Standby comparing its own configurations with the configurations downloaded from Active...

Startup XMLs are same, no reboot required
Standby continue...
ok

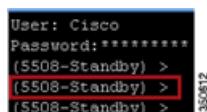

Starting LWAPP: ok
Starting CAPWAP: ok
Starting LACP: ok
Starting Security Services: ok
Starting Policy Manager: ok
Starting Authentication Engine: ok

350611

```

- After SSO is enabled, WLC is rebooted, and the XML configuration is synced, WLC 1 will transition its state to Active and WLC 2 will transition its state to Standby HOT. From this point onwards, GUI/Telnet/SSH for WLC 2 on the management interface will not work, as all the configurations and management should be done from the Active WLC. If required, the Standby WLC (WLC 2, in this example) can only be managed via the Console or Service Port.

Also, once the Peer WLC transitions to the Standby Hot state, -Standby keyword is automatically appended to the Standby WLCs prompt name.

- Complete these steps in order to check the redundancy status:

- For WLC 1, go to **Monitor > Redundancy > Summary**:

```
(5508) >show redundancy summary
Redundancy Mode = SSO ENABLED
  Local State = ACTIVE
  Peer State = STANDBY HOT
  Unit = Primary
  Unit ID = 00:24:97:69:D2:20
  Redundancy State = SSO
  Mobility MAC = 00:24:97:69:D2:20

  Average Redundancy Peer   Reachability Latency = 492 usecs
  Average Management Gateway Reachability Latency = 600 usecs

  Redundancy Management IP Address..... 9.6.61.21
  Peer Redundancy Management IP Address..... 9.6.61.23
  Redundancy Port IP Address..... 169.254.61.21
  Peer Redundancy Port IP Address..... 169.254.61.23
  Peer Service Port IP Address..... 0.0.0.0
```

- b. For WLC 2, go to Console connection:

```
(5508-Standby) >show redundancy summary
Redundancy Mode = SSO ENABLED
  Local State = STANDBY HOT
  Peer State = ACTIVE
  Unit = Secondary - HA SKU
  Unit ID = 00:24:97:69:76:20
  Redundancy State = SSO
  Mobility MAC = 00:24:97:69:D2:20

  Average Redundancy Peer   Reachability Latency = 481 usecs
  Average Management Gateway Reachability Latency = 2603 usecs

  Redundancy Management IP Address..... 9.6.61.23
  Peer Redundancy Management IP Address..... 9.6.61.21
  Redundancy Port IP Address..... 169.254.61.23
  Peer Redundancy Port IP Address..... 169.254.61.21
```

**Note:** Once SSO is enabled, the Standby WLC can be accessed via console connection or via SSH on the service port and on the redundant management interface.

## Disabling SSO on HA Pair

- On primary controller, disable SSO using the command:

### **Config redundancy mode disable**

The Active and Standby WLCs reboot once this command is executed.

The standby controller, when it comes back after the reboot, has the same IP address on interfaces as the primary controller and all the ports disabled.

- On the standby controller, re-enter the correct IP addresses corresponding to the management and dynamic interfaces and execute the following command:

### **Config port adminmode all enable**

- Save the configuration on the controller.

- To re-enable SSO, execute the command **Config redundancy sso** on the primary and secondary controllers.

## Configuring HA from the GUI

Both controllers reboot and pair up in the SSO mode. The standby will sync its configuration from the primary and come back in Hot-standby mode.

## Configuring HA from the GUI

Complete these steps:

1. Before you configure HA, it is mandatory to have both the controllers' management interface in the same subnet: WLC 1 and WLC2:
2. HA is disabled by default. Before you enable HA, it is mandatory to configure the Redundancy Management IP Address and the Peer Redundancy Management IP Address.

Both interfaces should be in the same subnet as the Management Interface. In this example, 10.70.0.12 is the Redundancy Management IP Address for WLC 1, and 10.70.0.13 is the Redundancy Management IP Address for WLC 2. It needs to be configured on WLC 2 where 10.70.0.13 is the Redundancy Management IP Address of WLC 2 and 10.70.0.12 is the Redundancy Management IP Address of WLC 1.

Enter the IP Address for both interfaces, and click Apply.

Global Configuration		
Redundancy Mgmt Ip <sup>1</sup>	10.70.0.13	
Peer Redundancy Mgmt Ip	10.70.0.12	
Redundancy port Ip	169.254.0.13	
Peer Redundancy port Ip	169.254.0.12	
Redundant Unit	Primary	
Mobility Mac Address	00:B0:E1:F2:C2:80	
Keep Alive Timer (100 - 1000) <sup>2, 3</sup>	100	milliseconds
Keep Alive Retries (3 - 10) <sup>3</sup>	3	
Peer Search Timer (60 - 300)	120	seconds
Management Gateway Failover	Enabled	
SSO	Enabled	
Service Port Peer Ip <sup>4</sup>	0.0.0.0	
Service Port Peer Netmask <sup>4</sup>	0.0.0.0	

3. Configure one WLC as Primary and the other WLC as Secondary from the Redundant Unit drop-down list. In this example, WLC 1 is configured as Primary and WLC 2 is configured as Secondary. Once configured, click Apply.

WLC 1:

## Configuring HA from the GUI

The screenshot shows the 'Global Configuration' section of the Cisco WLC 2 interface. The 'Redundancy' section is highlighted with a red box. The 'Redundant Unit' dropdown menu is open, showing 'Primary' as the selected option.

	Value
Redundancy Mgmt Ip <sup>1</sup>	10.70.0.13
Peer Redundancy Mgmt Ip	10.70.0.12
Redundancy port Ip	169.254.0.13
Peer Redundancy port Ip	169.254.0.12
Redundant Unit	Primary
Mobility Mac Address	00:B0:E1:F2:C2:80
Keep Alive Timer (100 - 1000) <sup>2, 3</sup>	100
Keep Alive Retries (3 - 10) <sup>3</sup>	3
Peer Search Timer (60 - 300)	120
Management Gateway Failover	Enabled
SSO	Enabled
Service Port Peer Ip <sup>4</sup>	0.0.0.0
Service Port Peer Netmask <sup>4</sup>	0.0.0.0

WLC 2:

On the Standby controller configure Redundancy Unit as **Secondary**.

The screenshot shows the 'Global Configuration' section of the Cisco WLC 2 interface. The 'Redundancy' section is highlighted with a red box. The 'Redundant Unit' dropdown menu is open, showing 'Secondary' as the selected option.

	Value
Redundancy Mgmt Ip <sup>1</sup>	10.70.0.12
Peer Redundancy Mgmt Ip	10.70.0.13
Redundancy port Ip	0.0.0.0
Peer Redundancy port Ip	169.254.0.0
Redundant Unit	Secondary
Mobility Mac Address	00:B0:E1:F2:D8:80
Keep Alive Timer (100 - 1000) <sup>2, 3</sup>	100
Keep Alive Retries (3 - 10) <sup>3</sup>	3
Peer Search Timer (60 - 300)	120
Management Gateway Failover	Enabled
Link encryption	Enabled
SSO	Enabled
Service Port Peer Ip <sup>4</sup>	0.0.0.0
Service Port Peer Netmask <sup>4</sup>	0.0.0.0

## Configuring HA from the GUI

4. Enabling SSO will reboot the WLCs in order to negotiate the HA role as per the configuration performed. Once the role is determined, configuration is synced from the Active WLC to the Standby WLC via the Redundant Port. Initially WLC configured, as Secondary will report XML mismatch and will download the configuration from Active and reboot again. During the next reboot after role determination, it will validate the configuration again, report no XML mismatch, and will process further in order to establish itself as the Standby WLC.

These are the boot-up logs from both the WLCs:

WLC 1:

```

Starting Switching Services: ok
Starting QoS Services: ok
Starting Policy Manager: ok
Starting Data Transport Link Layer: ok
Starting Access Control List Services: ok
Starting Client Troubleshooting Service: ok
Starting Management Frame Protection: ok
Starting Certificate Database: ok
Starting VPN Services: ok
Starting Licensing Services: ok
Starting Redundancy: Starting Peer Search Timer of 120 seconds
Found the Peer. Starting Role Determination...
Starting LWAPP: ok
Starting CAPWAP: ok
Starting LOCP: ok
Starting Security Services: ok
Starting Policy Manager: ok
Starting Authentication Engine: ok
Starting Mobility Management: ok
Starting Virtual AP Services: ok

```

350822

WLC on first reboot after enabling SSO:

```

Starting Client Troubleshooting Service: ok
Starting Management Frame Protection: ok
Starting Certificate Database: ok
Starting VPN Services: ok
Starting Licensing Services: ok
Starting Redundancy: Starting Peer Search Timer of 120 seconds
Found the Peer. Starting Role Determination...
Standby started downloading configurations from Active...
Standby comparing its own configurations with the configurations downloaded from Active...
Startup XMLs are different, reboot required
New XML downloaded Category: rsyncmgrXferTransport.
Restarting system ..
Restarting system.

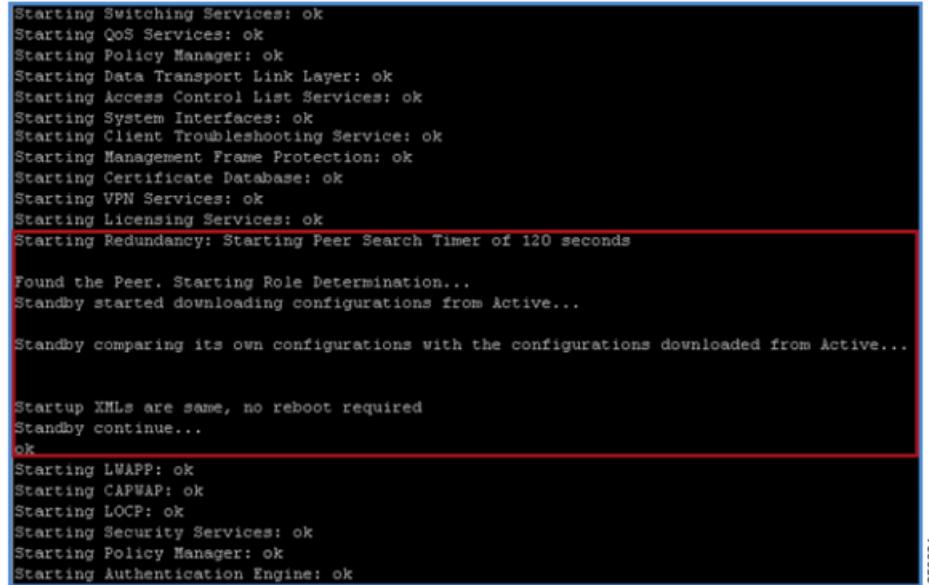

```

350823

**Note:** Once SSO is enabled, the Standby WLC can be accessed via console connection or via SSH on the service port and on the redundant management interface.

WLC 2 on second reboot after downloading XML configuration from Active:

## Configuring HA from the GUI

```

Starting Switching Services: ok
Starting QoS Services: ok
Starting Policy Manager: ok
Starting Data Transport Link Layer: ok
Starting Access Control List Services: ok
Starting System Interfaces: ok
Starting Client Troubleshooting Service: ok
Starting Management Frame Protection: ok
Starting Certificate Database: ok
Starting VPN Services: ok
Starting Licensing Services: ok
Starting Redundancy: Starting Peer Search Timer of 120 seconds

Found the Peer. Starting Role Determination...
Standby started downloading configurations from Active...

Standby comparing its own configurations with the configurations downloaded from Active...

Startup XMLs are same, no reboot required
Standby continue...
ok

Starting LWAPP: ok
Starting CAPWAP: ok
Starting LOCP: ok
Starting Security Services: ok
Starting Policy Manager: ok
Starting Authentication Engine: ok

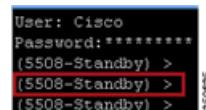

```

350624

- After SSO is enabled, WLC is rebooted, and the XML configuration is synced, WLC 1 transitions its state as Active and WLC 2 transitions its state to STANDBY HOT. From this point onwards, GUI/Telnet/SSH for WLC 2 on the management interface will not work, as all the configurations and management should be done from the Active WLC. If required, the Standby WLC (WLC 2, in this case) can only be managed via the Console or Service Port.

Also, once Peer WLC transitions to the STANDBY HOT state, the -Standby keyword is automatically appended to Standby WLCs prompt name.

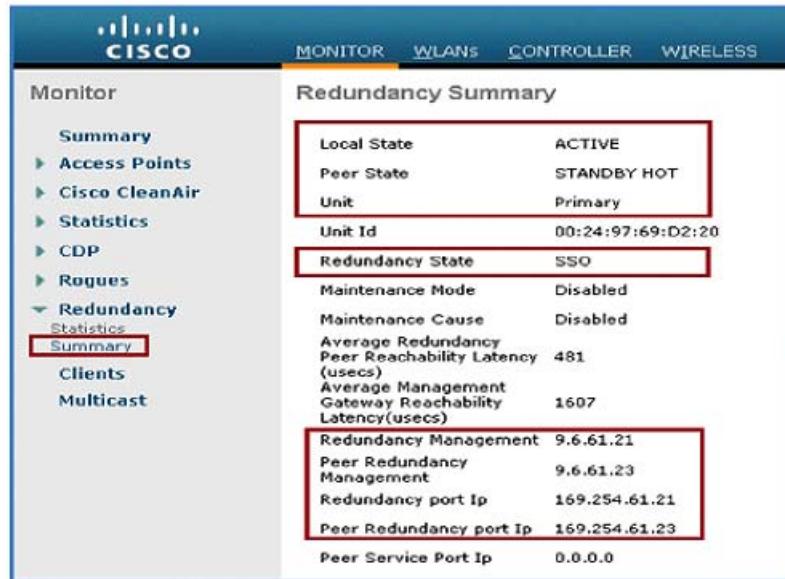

**Note:** Enable HA on the primary controller then 5 minutes later enable it on the secondary controller to force the primary to come up as Active..

- Complete these steps in order to check the redundancy status:

- For WLC 1, go to **Monitor > Redundancy > Summary**:

## Configuring HA from the GUI

- b. For WLC 2, go to Console connection:

```
(5508-Standby) >show redundancy summary
Redundancy Mode = SSO ENABLED
Local State = STANDBY HOT
Peer State = ACTIVE
Unit = Secondary - HA SKU
Unit ID = 00:24:97:69:70:20
Redundancy State = SSO
Mobility MAC = 00:24:97:69:D2:20

Average Redundancy Peer Reachability Latency = 481 usecs
Average Management Gateway Reachability Latency = 2603 usecs

Redundancy Management IP Address..... 9.6.61.23
Peer Redundancy Management IP Address..... 9.6.61.21
Redundancy Port IP Address..... 169.254.61.23
Peer Redundancy Port IP Address..... 169.254.61.21
```

**Note:** Once SSO is enabled, the Standby WLC can be accessed via console connection or via SSH on the service port and on the redundant management interface.

## Monitoring HA Redundancy in release 8.7

For Management - SNMP MIB is part of - **MIB CISCO-LWAPP-HA-MIB.my** is updated to capture the statistics discussed below.

By going to Monitor TAB on the controller and then choosing Redundancy, you can **Monitor Statistics**.

## Configuring HA from the GUI

**Redundancy Statistics**

**Category:** All **Clear**

**RF Client brief**

```

clientID = 0 clientSeq = 0
RF_INTERNAL_MSG
clientID = 4105 clientSeq = 1
SIM_INTERFACE_COMPONENT
clientID = 25 clientSeq = 69
CHKPT_RF
clientID = 35 clientSeq = 177 History
RF Client
clientID = 4100 clientSeq = 272
RF_CAPWAP client
  
```

**Gw Reachability Counters**

Gw Pings Successfully sent	1378052
Gw Pings Failed to send	0
Gw Responses Received	1378052
Current consecutive Gw Responses Lost	0
High Water Mark of Gw Responses Lost	1

**Network Latencies (RTT) for the Management Gateway Reachability in microsec**

Gateway Reachability Latency	usecs
1	599
2	605
3	622
4	611
5	597
6	589
7	607
8	590
9	619
10	569

**Transport Counters**

Number of messages in the hold Queue	0
Application message Max Size	8840
IPC message Max Size	8976
Time to hold IPC messages	100
IPC sequence number in the TX side	10998
IPC sequence number in the RX side	0
IPC sequence number mismatches(Low)	0
IPC sequence number mismatches(high)	0

**Ping Request and Response:**

Ping Requests sent to Peer	21
Ping Response received from Peer	0

## Configuring HA from the GUI

Keepalive Counters		Config Sync Counter	
Keep Alive Request Received	13780480	Usmdb Functions sent for Sync	
Keep Alive Responses Received	6890318	Failed sync for Usmdb Sync	
Keep Alive Request Sent	6890318	UsmDbs which failed to sync from Active to Standby	
Keep Alive Response Sent	13780480	Index Failed UsmDb	
Keep Alive Requests failed to send	0		
Keep Alive Responses to failed to send	0		
Number of times two Keepalives are lost consecutively	0		
Network Latencies (RTT) for the Peer Reachability in microseconds		Port Information	
Peer Reachability Latency usecs		Local Physical Ports	1,3
1	166	Peer Physical Ports	1,3,4
2	160		
3	165		
4	165		
5	165		
6	176		
7	175		
8	163		
9	168		
10	167		

On the same tab by selecting Summary, you can see Redundancy summary of the Active Controller.

The screenshot shows the Cisco Wireless LAN Controller (WLC) interface. The top navigation bar includes tabs for MONITOR, WLANs, CONTROLLER, WIRELESS, SECURITY, and MANAGEMENT. The MONITOR tab is selected. On the left, there's a sidebar with various monitoring links like Access Points, Cisco CleanAir, Statistics, CDP, Rogues, Redundancy, Clients, Sleeping Clients, Multicast, Applications, Lync, Local Profiling, and Cloud Services. Under the Redundancy link, the 'Summary' option is selected and highlighted with a red box. The main content area is titled 'Redundancy Summary' and contains the following table:

Local State	ACTIVE
Peer State	STANDBY HOT
Unit	Primary
Unit Id	00:B0:E1:F2:C2:80
Redundancy State	SSO
Maintenance Mode	Disabled
Maintenance Cause	Disabled
Average Redundancy Peer Reachability Latency (usecs)	176
Average Management Gateway Reachability Latency(usecs)	584
BulkSync Status	Complete

## Configuring HA from the GUI

The new enhancement in the 8.7 release is the **Peer Statistics** with additional information about Peer Serial Number and Fan Status.

The screenshot shows the Cisco Aironet Monitor interface. The top navigation bar includes links for MONITOR, WLANs, CONTROLLER, WIRELESS, SECURITY, and MANAGEMENT. The MONITOR tab is selected. On the left, a sidebar menu lists various monitoring categories: Summary, Access Points, Cisco CleanAir, Statistics, CDP, Rogues, Redundancy (with sub-options: Statistics, Peer Statistics, Summary, and Detail), Clients, Sleeping Clients, Multicast, Applications, Lync, Local Profiling, and Cloud Services. The 'Redundancy Detail' link under the Redundancy category is highlighted with a red box. The main content area displays the 'Redundancy Detail' page. It shows configuration details for redundancy management:

Redundancy Management	10.70.0.13
Peer Redundancy Management	10.70.0.12
Redundancy port Ip	169.254.0.13
Peer Redundancy port Ip	169.254.0.12
Peer Service Port Ip	0.0.0.0

Below this is a 'Switchover History Table' with columns: Previous Active, Current Active, Switchover Reason, and Switchover Time. Under 'Redundancy Timeout Values', it shows:

Keep Alive TimeOut	100	milliseconds
Peer Search TimeOut	120	seconds

Finally, there is a 'Network Routes Peer' section showing the number of routes: 0.

## Configuring HA from the GUI

Top-most releasable space.....: 131216 bytes (128.14 KB)  
Total allocated (incl mmap)....: 2134561600 bytes (1.98 GB)  
Total used (incl mmap).....: 2070452128 bytes (1.92 GB)  
Total free (incl mmap).....: 64109472 bytes (61.14 MB)
```

```
Peer system Power supply statistics:  
Power Supply 1..... Present, OK  
Power Supply 2..... Absent  
Serial Number..... FCH1921V24U  
Fan Status..... OK
```

## Configure HA from the Configuration Wizard

Complete these steps:

1. HA between two WLCs can also be enabled from the configuration wizard. It is mandatory to configure the Management IP Address of both the WLCs in same subnet before you enable HA.

WLC 1:

## Configure HA from the Configuration Wizard

```

System Name [Cisco_69:d2:24] (31 characters max): 5508
Enter Administrative User Name (24 characters max): Cisco
Enter Administrative Password (3 to 24 characters): *****
Re-enter Administrative Password : *****

Service Interface IP Address Configuration [static][DHCP]: static
Service Interface IP Address: 10.10.10.10
Service Interface Netmask: 255.255.255.0

Enable Link Aggregation (LAG) [yes][NO]:

Management Interface IP Address: 9.6.61.2
Management Interface Netmask: 255.255.255.0
Management Interface Default Router: 9.6.61.1
Management Interface VLAN Identifier (0 = untagged): 61
Management Interface Port Num [1 to 8]: 1
Management Interface DHCP Server IP Address: 9.1.0.100

```

WLC 2:

```

System Name [Cisco_69:78:24] (31 characters max): 5508
Enter Administrative User Name (24 characters max): Cisco
Enter Administrative Password (3 to 24 characters): *****
Re-enter Administrative Password : *****

Service Interface IP Address Configuration [static][DHCP]: static
Service Interface IP Address: 10.10.10.11
Service Interface Netmask: 255.255.255.0

Enable Link Aggregation (LAG) [yes][NO]:

Management Interface IP Address: 9.6.61.3
Management Interface Netmask: 255.255.255.0
Management Interface Default Router: 9.6.61.1
Management Interface VLAN Identifier (0 = untagged): 61
Management Interface Port Num [1 to 8]: 1
Management Interface DHCP Server IP Address: 9.1.0.100

```

- 2.** Once the Management IP is configured, the wizard will prompt you to enable HA. Enter yes in order to enable HA, which is followed by the configuration of the Primary/Secondary Unit and the Redundancy Management and Peer Management IP Address.
- In this example, WLC 1 is configured as the Primary WLC, which will take the role of the Active WLC. WLC 2 is configured as Secondary, which will take the role of the Standby WLC.
  - After entering the Primary/Secondary Unit, it is mandatory to configure the Redundancy Management and the Peer Redundancy Management IP Address. Both the interfaces should be in the same subnet as the Management Interface. In this example, 9.6.61.21 is the Redundancy Management IP Address for WLC 1 and 9.6.61.23 is the Redundancy Management IP Address for WLC 2. It needs to be configured on WLC 2 where 9.6.61.23 is the Redundancy Management IP Address of WLC 2 and 9.6.61.21 is the Redundancy Management IP Address of WLC 1.

WLC 1:

## Configure HA from the Configuration Wizard

```

System Name [Cisco_69:d2:24] (31 characters max): 5508
Enter Administrative User Name (24 characters max): Cisco
Enter Administrative Password (3 to 24 characters): *****
Re-enter Administrative Password : *****

Service Interface IP Address Configuration [static][DHCP]: static
Service Interface IP Address: 10.10.10.10
Service Interface Netmask: 255.255.255.0

Enable Link Aggregation (LAG) [yes][NO] :

Management Interface IP Address: 9.6.61.2
Management Interface Netmask: 255.255.255.0
Management Interface Default Router: 9.6.61.1
Management Interface VLAN Identifier (0 = untagged): 61
Management Interface Port Num [1 to 8]: 1
Management Interface DHCP Server IP Address: 9.1.0.100

Enable HA [yes][NO]: yes
Configure HA Unit [PRIMARY][secondary]: Primary
Redundancy Management IP Address: 9.6.61.21
Peer Redundancy Management IP Address: 9.6.61.23
Virtual Gateway IP Address: 1.1.1.1

```

WLC 2:

```

System Name [Cisco_69:78:24] (31 characters max): 5508
Enter Administrative User Name (24 characters max): Cisco
Enter Administrative Password (3 to 24 characters): *****
Re-enter Administrative Password : *****

Service Interface IP Address Configuration [static][DHCP]: static
Service Interface IP Address: 10.10.10.11
Service Interface Netmask: 255.255.255.0

Enable Link Aggregation (LAG) [yes][NO] :

Management Interface IP Address: 9.6.61.3
Management Interface Netmask: 255.255.255.0
Management Interface Default Router: 9.6.61.1
Management Interface VLAN Identifier (0 = untagged): 61
Management Interface Port Num [1 to 8]: 1
Management Interface DHCP Server IP Address: 9.1.0.100

Enable HA [yes][NO]: yes
Configure HA Unit [PRIMARY][secondary]: secondary
Redundancy Management IP Address: 9.6.61.23
Peer Redundancy Management IP Address: 9.6.61.21
Virtual Gateway IP Address: 1.1.1.1

```

3. After you enable HA from the configuration wizard, continue to configure these legacy wizard parameters:

- Virtual IP Address
- Mobility Domain Name

## Configure HA from the Configuration Wizard

- SSID
- DHCP Bridging Mode
- Radius configuration
- Country Code
- NTP configuration, and so forth

The WLCs will reboot after you save the configuration at the end.

4. While booting, the WLCs will negotiate the HA role as per the configuration done. Once the role is determined, the configuration is synced from the Active WLC to the Standby WLC via the Redundant Port. Initially WLC is configured, as Secondary will report XML mismatch and will download the configuration from Active and reboot again. During the next reboot after role determination, it will validate the configuration again, report no XML mismatch, and process further in order to establish itself as the Standby WLC.

These are the boot-up logs from both the WLCs:

WLC 1:

```

Starting Switching Services: ok
Starting QoS Services: ok
Starting Policy Manager: ok
Starting Data Transport Link Layer: ok
Starting Access Control List Services: ok
Starting Client Troubleshooting Service: ok
Starting Management Frame Protection: ok
Starting Certificate Database: ok
Starting VPN Services: ok
Starting Licensing Services: ok
Starting Redundancy: Starting Peer Search Timer of 120 seconds
Found the Peer. Starting Role Determination...
Starting LWAPP: ok
Starting CAPWAP: ok
Starting LOCP: ok
Starting Security Services: ok
Starting Policy Manager: ok
Starting Authentication Engine: ok
Starting Mobility Management: ok
Starting Virtual AP Services: ok

```

350632

WLC 2 on first reboot after enabling HA:

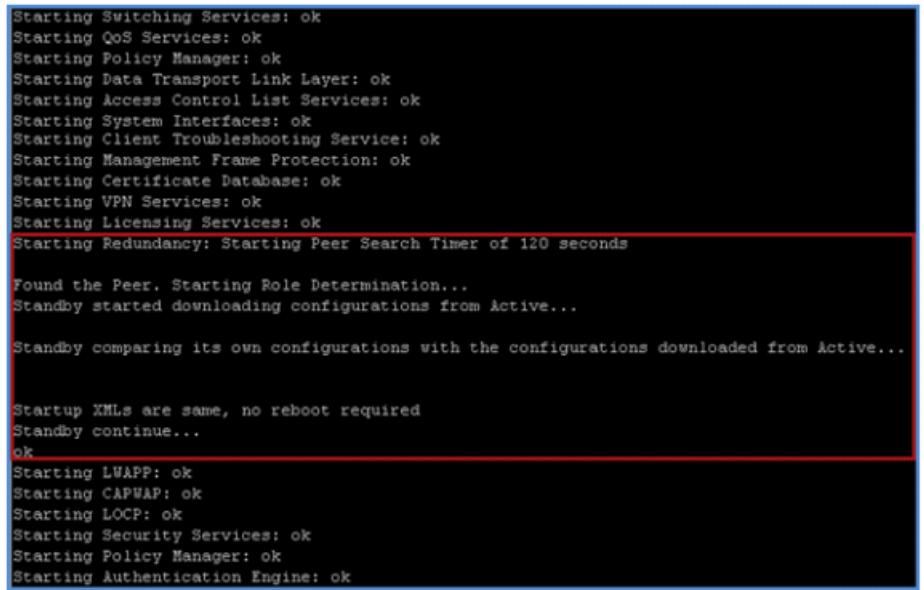

```

Starting Client Troubleshooting Service: ok
Starting Management Frame Protection: ok
Starting Certificate Database: ok
Starting VPN Services: ok
Starting Licensing Services: ok
Starting Redundancy: Starting Peer Search Timer of 120 seconds
Found the Peer. Starting Role Determination...
Standby started downloading configurations from Active...
Standby comparing its own configurations with the configurations downloaded from Active...
config interface address management 9.6.61.2 255.255.255.0 9.6.61.1
config interface address service-port 10.10.10.10 255.255.255.0
config coredump enable
config interface address management 9.6.61.3 255.255.255.0 9.6.61.1
config interface address service-port 10.10.10.11 255.255.255.0
Startup XMLs are different, reboot required
New XML downloaded Category: rsyncmgrXferTransport.
Restarting system ..
Restarting system.

```

WLC 2 on second reboot after downloading XML configuration from Active:

## Configure HA from the Configuration Wizard

```

Starting Switching Services: ok
Starting QoS Services: ok
Starting Policy Manager: ok
Starting Data Transport Link Layer: ok
Starting Access Control List Services: ok
Starting System Interfaces: ok
Starting Client Troubleshooting Service: ok
Starting Management Frame Protection: ok
Starting Certificate Database: ok
Starting VPN Services: ok
Starting Licensing Services: ok
Starting Redundancy: Starting Peer Search Timer of 120 seconds

Found the Peer. Starting Role Determination...
Standby started downloading configurations from Active...

Standby comparing its own configurations with the configurations downloaded from Active...

Startup XMLs are same, no reboot required
Standby continue...
ok

Starting LWAPP: ok
Starting CAPWAP: ok
Starting LOCP: ok
Starting Security Services: ok
Starting Policy Manager: ok
Starting Authentication Engine: ok

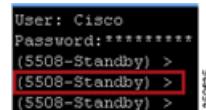

```

350634

**Note:** Once SSO is enabled, the Standby WLC can be accessed via console connection or via SSH on the service port and on the redundant management interface.

- After HA is enabled followed by WLC reboots and XML configuration is synced, WLC 1 will transition its state as Active and WLC 2 will transition its state as STANDBY HOT. From this point onwards GUI/Telnet/SSH for WLC 2 on management interface will not work, as all the configurations and management should be done from Active WLC. If required, the Standby WLC (WLC 2, in this case) can only be managed via the Console or Service Port.

Also, once the Peer WLC transitions to the STANDBY Hot state, the -Standby keyword is automatically appended to the Standby WLCs prompt name.

- Complete these steps in order to check the redundancy status:

- For WLC 1:

## Upgrade the WLC in HA Setup

```
(5508) >show redundancy summary
Redundancy Mode = SSO ENABLED
  Local State = ACTIVE
  Peer State = STANDBY HOT
    Unit = Primary
    Unit ID = 00:24:97:69:D2:20
  Redundancy State = SSO
    Mobility MAC = 00:24:97:69:D2:20

  Average Redundancy Peer      Reachability Latency = 486 usecs
  Average Management Gateway Reachability Latency = 2043 usecs

  Redundancy Management IP Address..... 9.6.61.21
  Peer Redundancy Management IP Address..... 9.6.61.23
  Redundancy Port IP Address..... 169.254.61.21
  Peer Redundancy Port IP Address..... 169.254.61.23
  Peer Service Port IP Address..... 10.10.10.11
```

- b. For WLC 2, go to Console connection:

```
(5508-Standby) >show redundancy summary
Redundancy Mode = SSO ENABLED
  Local State = STANDBY HOT
  Peer State = ACTIVE
    Unit = Secondary - HA SKU
    Unit ID = 00:24:97:69:78:20
  Redundancy State = SSO
    Mobility MAC = 00:24:97:69:D2:20

  Average Redundancy Peer      Reachability Latency = 506 usecs
  Average Management Gateway Reachability Latency = 676 usecs

  Redundancy Management IP Address..... 9.6.61.23
  Peer Redundancy Management IP Address..... 9.6.61.21
  Redundancy Port IP Address..... 169.254.61.23
  Peer Redundancy Port IP Address..... 169.254.61.21
```

**Note:** Once SSO is enabled, the Standby WLC can be accessed via console connection or via SSH on the service port and on the redundant management interface.

## Upgrade the WLC in HA Setup

### Upgrade Procedure in HA Setup

Complete these steps:

1. Copy the target image into your TFTP directory and go to the Web UI on your wireless LAN Controller.
2. Navigate to the download page located at **Commands -> Download** File and download the image to the active controller.
3. Once the image has downloaded to the primary and been extracted, the controller will upload the file to the standby controller.
4. You can now verify this image by using the CLI **show boot**. The target image will be shown as the default image and will be loaded on the next reload.

## Upgrade the WLC in HA Setup

5. Optional: Prime the AP's with the new image. You don't have to perform this step, but it will minimize network downtime as the AP's will not have to download a new image when the controller reboots as they will already have it.
6. Use the CLI: **config ap image predownload primary all**
7. This will push the primary image to all APs. This process may take some time depending on the number of APs present on the controller.
8. You can monitor the progress with the command **show ap image all**.
9. Once this is complete, reload the controllers. To ensure both controllers reload together use the command **reset system in <>**
10. Using this command will reboot both devices.
11. To minimize downtime even more you can add the **reset-aps** keyword at the end of the command. This will start the AP's reloading instead of waiting for the controller to come back with the new image.
12. Once the controller has come back, go to Wireless / Access Points and make sure all your AP's are coming back online and are running the correct image.

## Important Guidelines before Initiating a WLC Upgrade in HA Setup

- Service Upgrade is not supported in this release, so network downtime should be planned before you upgrade the WLCs in the HA setup.
- The peer should be in the Hot Standby state before you start the upgrade in the HA setup.
- It is recommended to reboot both the WLCs almost together after upgrade so that there is no software version mismatch.
- Schedule Reset applies to both the WLCs in the HA setup.
- The Standby WLC can be rebooted from the Active WLC using the **reset peer-system** command if a scheduled reset is not planned.
- Debug transfer can be enabled on the Active WLC as well as the Standby WLC.
- If Active WLC unexpectedly reboot between software download and reboot both WLCs, you need to reboot both WLCs in order to complete software upgrade.

## Download/Upload Facts in HA Setup

- No direct download and upload configuration is possible from the Standby WLC.
- All download file types like Image, Configuration, Web-Authentication bundle, and Signature Files will be downloaded on the Active WLC first and then pushed automatically to the Standby WLC.
- Once the configuration file is downloaded on the Active WLC, it is pushed to the Standby WLC. This results in the reset of the Standby WLC first, followed by the reset of the Active WLC.
- The Peer Service Port and Static route configuration is a part of a different XML file, and will not be applied if downloaded as part of the configuration file.
- The download of certificates should be done separately on each box and should be done before pairing.
- Uploading different file types like Configuration, Event Logs, Crash files, and so forth can be done separately from the Standby WLC. However, the CLI to configure different parameters for upload like Server IP, file type, path and name should be done on the Active WLC. Once the upload parameters are configured on the Active WLC, the **transfer upload peer-start** command should be issued on the Active WLC in order to initiate the upload from the Standby WLC.

## Failover Process in the HA Setup

- The service port state will be synced from the Active WLC to the Standby WLC. That is, if DHCP is enabled on the Active WLC service port, the Standby WLC will also use DHCP for getting the service port IP address. If the service port of the Active WLC is configured with a Static IP Address, the Standby WLC also needs to be configured with a different Static IP Address. The CLI to configure the IP Address for the Standby WLC service port is `configure redundancy interface address peer-service-port <IP Address>`. This command should be executed from the Active WLC. Also, in order to configure the route on the Standby WLC for out-of-band management on the service port, issue the `configure redundancy peer-route add <Network IP Address> <IP Mask> <Gateway>` command from the Active WLC.

## Failover Process in the HA Setup

In the HA setup, the AP's CAPWAP state is maintained on the Active WLC as well as the Standby WLC (only for APs which are in a Run state). That is, Up Time and Association Up Time is maintained on both the WLC, and when switchover is initiated, the Standby WLC takes over the network. In this example, WLC 1 is in an Active state and serving the network, and WLC 2 is in a Standby state monitoring the Active WLC. Although WLC 2 is in Standby state, it still maintains the CAPWAP state of the AP.

WLC 1:

(5508) >show ap uptime			
AP Name	Ethernet MAC	AP Up Time	Association Up Time
AP_3500E	c4:7d:4f:3a:07:74	0 days, 02 h 37 m 33 s	0 days, 02 h 36 m 22 s

350696

WLC 2:

(5508-Standby) >show ap uptime			
AP Name	Ethernet MAC	AP Up Time	Association Up Time
AP_3500E	c4:7d:4f:3a:07:74	0 days, 02 h 38 m 11 s	0 days, 02 h 37 m 00 s

350657

Failover for WLCs in HA setup can be categorized into two different sections:

### Box Failover

In the case of Box Failover (that is, the Active WLC crashes / system hang / manual reset / force switchover), the direct command is sent from the Active WLC via the Redundant Port as well as from the Redundant Management Interface to the Standby WLC to take over the network. This may take 5-100 msec depending on the number of APs in the network. In the case of power failure on the Active WLC or some crash where the direct command for switchover cannot be sent, it may take 350-500 msec depending on the number of APs in network.

The time it takes for failover in case of power failure on an Active Box also depends on the Keepalive timer configured on the WLC (configured for 100 msec by default). The algorithm it takes to decide the failover is listed here:

- The Standby WLC sends Keepalive to the Active WLC and expects an acknowledgment within 100 msec as per the default timer. This can be configured in range from 100-400 msec.
- If there is no acknowledgment of Keepalive within 100 msec, the Standby WLC immediately sends an ICMP message to the Active WLC via the redundant management interface in order to check if it is a box failover or some issue with Redundant Port connection.
- If there is no response to the ICMP message, the Standby WLC gets aggressive and immediately sends another Keepalive message to the Standby WLC and expects an acknowledgment in 25% less time (that is, 75 msec or 25% less of 100 msec).

## Failover Process in the HA Setup

- If there is no acknowledgment of Keepalive within 75 msec, the Standby WLC immediately sends another ICMP message to the Active WLC via the redundant management interface.
- Again, if there is no response for the second ICMP message, the Standby WLC gets more aggressive and immediately sends another Keepalive message to the Standby WLC and expects an acknowledgment in time further 25% of actual timer less from last Keepalive timer (that is, 50 msec or last Keepalive timer of 75 msec - 25% less of 100 msec).
- If there is no acknowledgment of the third Keepalive packet within 50 msec, the Standby WLC immediately sends another ICMP message to the Active WLC via the redundant management interface.
- Finally, if there is no response from the third ICMP packet, the Standby WLC declares the Active WLC is dead and assumes the role of the Active WLC.

**Network Failover**

In the case of a Network Failover (that is, the Active WLC cannot reach its gateway for some reason), it may take 3-4 seconds for a complete switchover depending on the number of APs in the network.

**Steps to Simulate Box Failover**

Complete these steps:

1. Complete the steps as explained in the configuration section in order to configure HA between two WLCs, and make sure before force switchover is initiated that both the WLCs are paired up as the Active WLC and the Standby WLC.

For WLC 1:

```
(5508) >show redundancy summary
Redundancy Mode = SSO ENABLED
  Local State = ACTIVE
  Peer State = STANDBY HOT
  Unit = Primary
  Unit ID = 00:24:97:69:D2:20
  Redundancy State = SSO
  Mobility MAC = 00:24:97:69:D2:20

  Average Redundancy Peer      Reachability Latency = 486 usecs
  Average Management Gateway Reachability Latency = 2043 usecs

  Redundancy Management IP Address..... 9.6.61.21
  Peer Redundancy Management IP Address..... 9.6.61.23
  Redundancy Port IP Address..... 169.254.61.21
  Peer Redundancy Port IP Address..... 169.254.61.23
  Peer Service Port IP Address..... 10.10.10.11
```

For WLC 2, go to Console connection:

## Failover Process in the HA Setup

```
(5508-Standby) >show redundancy summary
Redundancy Mode = SSO ENABLED
  Local State = STANDBY HOT
  Peer State = ACTIVE
    Unit = Secondary - HA SKU
    Unit ID = 00:24:97:69:78:20
  Redundancy State = SSO
    Mobility MAC = 00:24:97:69:D2:20

  Average Redundancy Peer   Reachability Latency = 506 usecs
  Average Management Gateway Reachability Latency = 676 usecs

  Redundancy Management IP Address..... 9.6.61.23
  Peer Redundancy Management IP Address..... 9.6.61.21
  Redundancy Port IP Address..... 169.254.61.23
  Peer Redundancy Port IP Address..... 169.254.61.21
```

2. Associate an AP to the WLC and check the status of the AP on both the WLCs. In the HA setup, a mirror copy of the AP database is maintained on both the WLCs. That is, APs CAPWAP state is maintained on Active as well as Standby WLC (only for APs which are in Run state) and when switchover is initiated, the Standby WLC takes over the network. In this example, WLC 1 is an Active WLC, WLC 2 is in a Standby state, and the AP database is maintained on both the WLCs.

WLC 1:

```
(5508) >show ap summary
Number of APs..... 1
Global AP User Name..... cisco
Global AP Dot1x User Name..... Not Configured

AP Name      Slots AP Model      Ethernet MAC      Location      Port Country Priority
AP_3500E     2     AIR-CAP3502E-A-K9  c4:7d:4f:3a:07:74          1           1

(5508) >show ap uptime
Number of APs..... 1
Global AP User Name..... cisco
Global AP Dot1x User Name..... Not Configured

AP Name      Ethernet MAC      AP Up Time      Association Up Time
AP_3500E     c4:7d:4f:3a:07:74  0 days, 04 h 27 m 55 s  0 days, 04 h 26 m 44 s
```

350860

WLC 2

```
(5508-Standby) >show ap summary
Number of APs..... 1
Global AP User Name..... cisco
Global AP Dot1x User Name..... Not Configured

AP Name      Slots AP Model      Ethernet MAC      Location      Port Country Priority
AP_3500E     2     AIR-CAP3502E-A-K9  c4:7d:4f:3a:07:74          1           1

(5508-Standby) >show ap uptime
Number of APs..... 1
Global AP User Name..... cisco
Global AP Dot1x User Name..... Not Configured

AP Name      Ethernet MAC      AP Up Time      Association Up Time
AP_3500E     c4:7d:4f:3a:07:74  0 days, 04 h 29 m 07 s  0 days, 04 h 27 m 56 s
```

350861

3. Create an open WLAN and associate a client to it. The client database is not synced on the Standby WLC, so the client entry will not be present on the Standby WLC. Once the WLAN is created on the Active WLC, it will also be synced to the Standby WLC via the Redundant Port.

WLC 1:

## Failover Process in the HA Setup

```
(5508) >show wlan summary
Number of WLANs..... 1
WLAN ID WLAN Profile Name / SSID Status Interface Name PMIPv6 Mobility
----- -----
1 Beta-Test / Beta-Test Enabled management none
(5508) >show client summary
Number of Clients..... 1
Number of PMIPv6 Clients..... 0
MAC Address AP Name Status WLAN/GLAN/RLAN Auth Protocol Port Wired PMIPv6
----- -----
00:40:96:b8:d4:be AP_3500E Associated 1 Yes 802.11a 1 No No
350862
```

WLC 2:

```
(5508-Standby) >show wlan summary
Number of WLANs..... 1
WLAN ID WLAN Profile Name / SSID Status Interface Name PMIPv6 Mobility
----- -----
1 Beta-Test / Beta-Test Enabled management none
(5508-Standby) >show client summary
Number of Clients..... 0
350839
```

- Issue the redundancy force-switchover command on the Active WLC. This command will trigger a manual switchover where the Active WLC will reboot and the Standby WLC will take over the network. In this case, the client on the Active WLC will be de-authenticated and join back on the new Active WLC.

WLC 1:

```
(5508) >redundancy force-switchover
This will reload the active unit and force a switch of activity. Are you sure? (y/N) y
System will now restart!
350864
```

WLC 2:

```
(5508-Standby) >
HA completed successfully, WLC switch over detection time : 0 msec and APs switch over time : 1 msec
(5508) >show client summary
Number of Clients..... 1
Number of PMIPv6 Clients..... 0
MAC Address AP Name Status WLAN/GLAN/RLAN Auth Protocol Port Wired PMIPv6
----- -----
00:40:96:b8:d4:be AP_3500E Associated 1 Yes 802.11a 1 No No
350865
```

**Note:** Observe that the prompt in this example changed from 5508-Standby to 5508. This is because this WLC is now the Active WLC and the time taken for AP switchover is 1 msec.

WLC 2:

## Failover Process in the HA Setup

(5508) >show ap uptime			
AP Name	Ethernet MAC	AP Up Time	Association Up Time
AP_3500E	c4:7d:4f:3a:07:74	0 days, 06 h 13 m 07 s	0 days, 06 h 11 m 56 s

350686

Observe the AP CAPWAP State on WLC 2, which was the Standby WLC initially and is now the Active WLC after switchover. AP Up Time as well as Association Up Time is maintained, and the AP did not go in to the discovery state.

These matrices provide a clear picture of what condition the WLC Switchover will trigger:

## Failover Process in the HA Setup

Network Issues					
RP Port Status	Peer Reachable via Redundant Management	Gateway Reachable from Active	Gateway Reachable from Standby	Switchover	Results
Up	Yes	Yes	Yes	No	No Action
Up	Yes	Yes	No	No	Standby will reboot and check for gateway reachability. Will go into maintenance mode if still not reachable.
Up	Yes	No	Yes	Yes	Switchover happens
Up	Yes	No	No	No	No Action
Up	No	Yes	Yes	No	No Action
Up	No	Yes	No	No	Standby will reboot and check for gateway reachability. Will go into maintenance mode if still not reachable.
Up	No	No	Yes	Yes	Switchover happens
Up	No	No	No	No	No Action
Down	Yes	Yes	Yes	No	Standby will reboot and check for gateway reachability. Will go into maintenance mode if still not reachable.
Down	Yes	Yes	No	No	Standby will reboot and check for gateway reachability. Will go into maintenance mode if still not reachable.
Down	Yes	No	Yes	No	Standby will reboot and check for gateway reachability. Will go into maintenance mode if still not reachable.
Down	Yes	No	No	No	Standby will reboot and check for gateway reachability. Will go into maintenance mode if still not reachable.
Down	No	Yes	Yes	Yes	Switchover happens and this may result in Network Conflict
Down	No	Yes	No	No	Standby will reboot and check for gateway reachability. Will go into maintenance mode if still not reachable.
Down	No	No	Yes	Yes	Switchover happens
Down	No	No	No	No	Standby will reboot and check for gateway reachability. Will go into maintenance mode if still not reachable.

Trigger	RP Port Status	Peer Reachable via Redundant Management	Switchover	Result
System Hang	No	No	Yes	As Updated in Network Issue section
Manual Reset	No	No	Yes	As Updated in Network Issue section
Force Switchover	No	No	Yes	As Updated in Network Issue section

## HA Facts

- HA Pairing is possible only between the same type of hardware and software versions. Mismatch may result in Maintenance Mode. The Virtual IP Address should be the same on both the WLCs before configuring SSO.
- Direct connectivity is recommended between the Active and Standby Redundant Port for 3500, 5500 and 8500 series of WLCs.
- WiSM-2 WLCs should be in same 6500 chassis or can be installed in VSS setup for reliable performance.
- A physical connection between Redundant Port and Infrastructure Network should be done prior to HA configuration.
- The Primary units MAC should be used as Mobility MAC in the HA setup in order to form a mobility peer with another HA setup or independent controller. You also have the flexibility to configure a custom MAC address, which can be used as a Mobility MAC address using the `configure redundancy mobilitymac <custom mac address>` command. Once configured, you should use this MAC address to form a mobility peer instead of using the system MAC address. Once HA is configured, this MAC cannot be changed.
- It is recommended that you use DHCP address assignment for the service port in the HA setup. After HA is enabled, if the static IP is configured for service port, WLC loses the service port IP and it has to be configured again.
- When SSO is enabled, there is no SNMP/GUI access on the service port for both the WLCs in the HA setup.
- Configurations like changing virtual IP address, enabling secureweb mode, configuring web auth proxy, and so forth need a WLC reboot in order to get implemented. In this case, a reboot of the Active WLC will also trigger a simultaneous reboot of the Standby WLC.
- When SSO is disabled on the Active WLC, it will be pushed to the Standby WLC. After reboot, all the ports will come up on the Active WLC and will be disabled on the Standby WLC.
- Keepalive and Peer Discovery timers should be left with default timer values for better performance.
- Clear configuration on the Active WLC will also initiate clear configuration on the Standby WLC.

## SSO Deployment with Legacy Primary/Secondary/Tertiary HA

- Internal DHCP is not supported when SSO is enabled.
- With versions 7.5 and above, AP/Client SSO supports synchronization of L3 MGID between active and standby controllers.
- APs with LSC certificates are supported. The controller's LSC certificate and SCEP configuration must be implemented on the active and standby controllers before activating SSO.
- From Release 8.0.132.0 onwards, mobility MAC configuration is no longer present in the uploaded configuration. Therefore, if you download this configuration file back to the controller, you must add **config redundancy mobilitymac mac\_addr** in the config file before download.

**Note:** Upon a switchover, the behavior of the mobility peer depends on the version running on the anchor and foreign controllers. When both anchor and foreign controllers are running version 7.5 or higher, roamed clients are not impacted and the peer sends back the AP list, shun list, and Infrastructure MFP keys to the new active controller upon receiving a switchover message. In a mobility group that has a mix of WLCs running versions lower than 7.5 which supports HA (7.3 and 7.4) and WLCs running versions 7.5 or higher, when a switchover occurs, the roamed clients will be cleaned up on both the anchor and foreign WLCs. Therefore, it is recommended to have a mobility group with WLCs running image versions 7.5 and higher, when an HA Pair is present in the mobility group. If the WLC mobility peer version is older than 7.3, which does not support HA, this problem does not exist.

## Maintenance Mode

There are few scenarios where the Standby WLC may go into Maintenance Mode and not be able to communicate with the network and peer:

- Non reachability to Gateway via Redundant Management Interface
- WLC with HA SKU which had never discovered peer
- Redundant Port is down
- Software version mismatch (WLC which boots up first goes into active mode and the other WLC in Maintenance Mode)

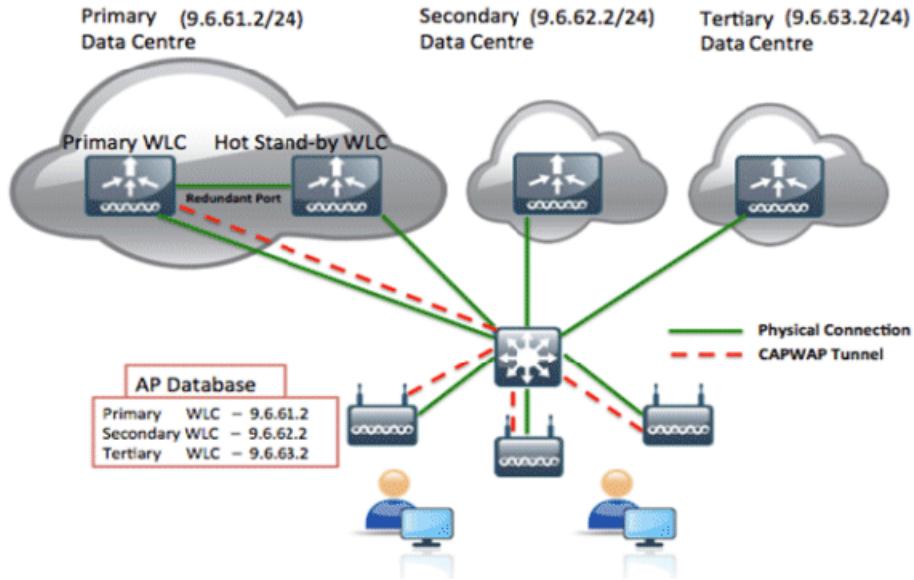

```
(5508-Standby) >show redundancy summary
Redundancy Mode = SSO ENABLED
  Local State = NEGOTIATION
  Peer State = DISABLED
    Unit = Secondary - HA SKU
    Unit ID = 00:24:97:69:78:20
  Redundancy State = Non Redundant
    Mobility MAC = 00:24:97:69:02:20
  Maintenance Mode = Enabled
  Maintenance cause= Negotiation Timeout
Redundancy Management IP Address..... 9.6.61.23
Peer Redundancy Management IP Address..... 9.6.61.21
Redundancy Port IP Address..... 169.254.61.23
Peer Redundancy Port IP Address..... 169.254.61.21
```

**Note:** The WLC should be rebooted in order to bring it out of Maintenance Mode. Only the Console and Service Port is active in Maintenance Mode.

## SSO Deployment with Legacy Primary/Secondary/Tertiary HA

HA (that is, AP SSO) can be deployed with Secondary and Tertiary Controllers just like today. Both Active and Standby WLCs combined in the HA setup should be configured as primary WLC. Only on failure of both Active and Standby WLCs in the HA setup will the APs fall back to Secondary and further to Tertiary WLCs.

## SSO Deployment in Mobility Setup

## SSO Deployment in Mobility Setup

Each WLC has its own unique MAC address, which is used in mobility configuration with an individual controller management IP address. In HA (that is, AP SSO) setup, both the WLCs (Primary and Standby) have their own unique MAC address. In the event of failure of the Primary box and Standby takes over the network if the MAC address of the Primary box is used on another controllers in mobility setup, control path and data path will be down and user has to manually change the MAC to standby MAC address on all the controllers in mobility setup. This is a really cumbersome process as a lot of manual intervention is required.

In order to keep the mobility network stable without any manual intervention and in the event of failure or switchover, the back-and-forth concept of Mobility MAC has been introduced. When the HA pair is set up, by default, the Primary WLC's MAC address is synced as the Mobility MAC address on the Standby WLC which can be seen via the show redundancy summary command on both the controllers.

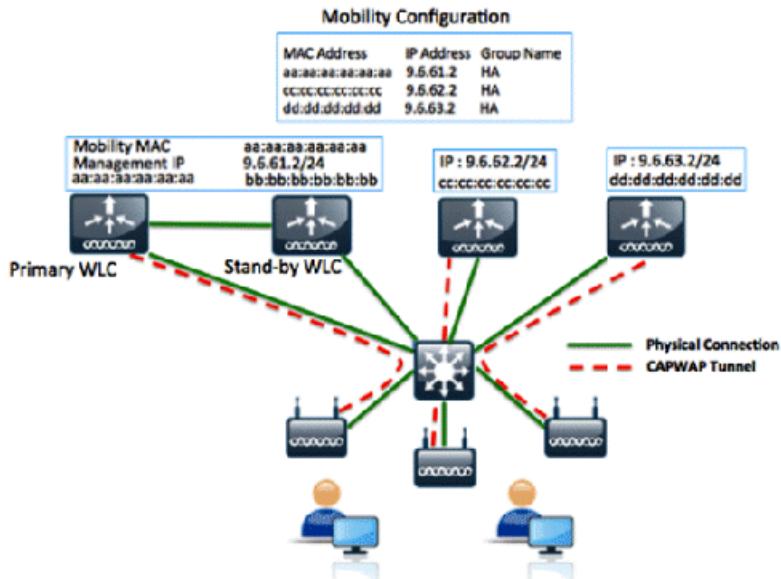

```
(5508-Standby) >show redundancy summary
Redundancy Mode = SSO ENABLED
Unit = Secondary - HA SKU
Unit ID = 00:24:97:69:78:20
Redundancy State = Non Redundant
Mobility MAC = 00:24:97:69:D2:20 ←

Redundancy Management IP Address..... 9.6.61.23
Peer Redundancy Management IP Address..... 9.6.61.21
Redundancy Port IP Address..... 169.254.61.23
Peer Redundancy Port IP Address..... 169.254.61.21
```

In this output, captured from a Standby controller, the Mobility MAC address can be observed, which is different from the Standby's own MAC address seen as Unit ID. This MAC address is synced from the Active WLC and should be used in mobility configuration. With this implementation, if the Active WLC goes down or even if it is replaced, the Mobility MAC address is still available and active on the Standby WLC. In case the new controller is introduced in the network because of the replacement of the previous Active WLC, it will transition its state as Standby and the same Mobility MAC address is synced again to the new Standby WLC.

## Licensing for HA Pair

You have the flexibility to configure a custom MAC address as Mobility MAC instead of using the default behavior of using the Active WLC MAC address as Mobility MAC. This can be done using the `configure redundancy mobilitymac <custom mac address>` command on the Active WLC. Once configured, you should use this MAC address on other controllers in order to form a mobility peer instead of using the Active WLC MAC address. This MAC address should be configured before forming the HA pair. Once the HA pair is formed, the Mobility MAC cannot be changed or edited.

In this topology, the Primary and Standby have their own MAC address. With HA pairing, the Active WLC MAC address is synced as a Mobility MAC address, which is the default behavior if a custom MAC is not configured before HA pairing. Once the Active WLC MAC address is synced as the Mobility MAC address, the same MAC is used in mobility configuration on all the controllers in the mobility setup.

## Licensing for HA Pair

A HA Pair can be established between two WLCs running in these combinations:

- One WLC has a valid AP Count license and the other WLC has a HA SKU UDI
- Both the WLCs have a valid AP Count license
- One WLC has an Evaluation license and the other WLC has a HA SKU UDI or Permanent license

## One WLC has a valid AP Count license and the other WLC has a HA SKU UDI

- HA SKU is a new SKU with a Zero AP Count License.
- The device with HA SKU becomes Standby the first time it pairs up.
- AP-count license info will be pushed from Active to Standby.
- On event of Active failure, HA SKU will let APs join with AP-count obtained and will start 90-day countdown. The granularity of this is in days.
- After 90-days, it starts nagging messages. It will not disconnect connected APs.
- With new WLC coming up, HA SKU at the time of paring will get the AP Count:
  - If the new WLC has a higher AP count than the previous, the 90-day counter is reset.

- If the new WLC has a lower AP count than the previous, the 90-day counter is not reset.
- In order to lower AP count after switchover, the WLC offset timer will continue and nagging messages will be displayed after time expiry.
  - Elapsed time and AP-count will be remembered on reboot.
  - The factory default HA-SKU controller should not allow any APs to join.

## Both the WLCs have a valid AP Count license

- The CLI should be used to configure one WLC as the Standby WLC (as mentioned in the configuration section) provided it satisfies the requirement of minimum permanent license count. This condition is only valid for the 5508 WLC, where a minimum of 50 AP Permanent licenses are needed to be converted to Standby. There is no restriction for other WLCs such as the 5520, WiSM2, 7500, and 8500.
- AP-count license information will be pushed from Active to Standby.
- In the event of a switchover, the new Active WLC will operate with the license count of the previous Active WLC and will start the 90-day countdown.
- The WLC configured as Secondary will not use its own installed license, and only the inherited license from the active will be utilized.
- After 90-days, it starts nagging messages. It will not disconnect connected APs.
- With the new WLC coming up, HA SKU at the time of paring will get the AP Count:
  - If the new WLC has a higher AP count than the previous, the 90-day counter is reset.
  - If the new WLC has a lower AP count than the previous, the 90-day counter is not reset.
  - After switchover to a lower AP count, the WLC offset timer will continue and nagging messages will be displayed after time expiry.

## One WLC has an Evaluation license and the other WLC has a HA SKU UDI or Permanent license

- The device with HA SKU becomes the Standby WLC the first time it pairs up with an existing Active WLC running Evaluation License. Or, any WLC running a permanent license count can be configured as the Secondary unit using the CLI configuration provided if it satisfies the requirement of minimum permanent license count. This condition is only valid for the 5508 WLC, where a minimum of 50 AP Permanent licenses are needed to be converted to Standby. There is no restriction for other WLCs such as the 5520, WiSM2, 7500, 3504 and 8500.
- AP-count license information will be pushed from Active to Standby.
- In the event of a switchover, the new Active WLC will operate with the license count of the previous Active WLC and start the 90-day countdown.
- After 90-days, it starts nagging messages. It will not disconnect connected APs.
- With new the WLC coming up, HA SKU at the time of paring will get the AP Count:
  - If the new WLC has a higher AP count than the previous, the 90-day counter is reset.
  - If the new WLC has a lower AP count than the previous, the 90-day counter is not reset.
  - After switchover to a lower AP count, the WLC offset timer will continue and nagging messages will be displayed after time expiry.

## Supported HA Topologies

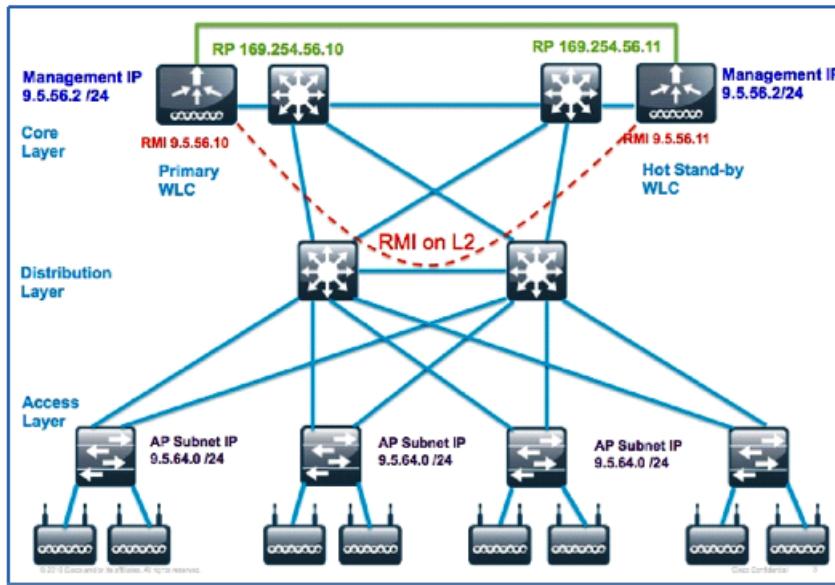

### Supported HA Topologies in Release 7.5-8.7

#### 3500(rel 8.5)/5500/7500/8500 Series Controllers

1. Back-to-back Redundancy Port (RP) connectivity between the two WLCs, Redundancy Management Interface (RMI) connectivity to check peer and management gateway reachability.
2. RP connectivity with L2 adjacency between the two WLCs, RMI connectivity to check peer and management gateway reachability. This can be within the same or different data centers.
3. Two 5508, 7500 or 8500 connected to a VSS pair. Primary WLC connected to one 6500 and the Stand-by WLC to the other 6500.

#### Back-to-back RP Connectivity

**Figure 1 Back-to-back RP connectivity**

- This is the same topology as was supported in controller release 7.3.
- Configuration Sync and Keepalive messages are sent via Redundancy Port.
- RMI interface is created as part of Management subnet and is used to check peer and management gateway reachability.
- RTT Latency is 80 milliseconds by default. The RTT should be 80% of the Keepalive timer which is configurable in the range 100-400 milliseconds.
- Failure detection time is  $3 \times 100 + 60 + \text{jitter}$  (12 msec) = ~400 msec

**Note:** In the above equation, 3 is the Keepalive retry count, 100 is the Keepalive timer, and 60 is  $3 \times 10 + 3 \times 10$  (3 RMI pings to peer + 3 pings to gateway).

- Bandwidth: 60 Mbps or more

## Supported HA Topologies

- MTU: 1500

**Configuration on Primary WLC:**

```
configure interface address management 9.5.56.2 255.255.255.0 9.5.56.1
```

```
configure interface address redundancy-management 9.5.56.10 peer-redundancy-management 9.5.56.11
```

```
configure redundancy unit primary
```

```
configure redundancy mode sso
```

**Configuration on Hot Standby WLC:**

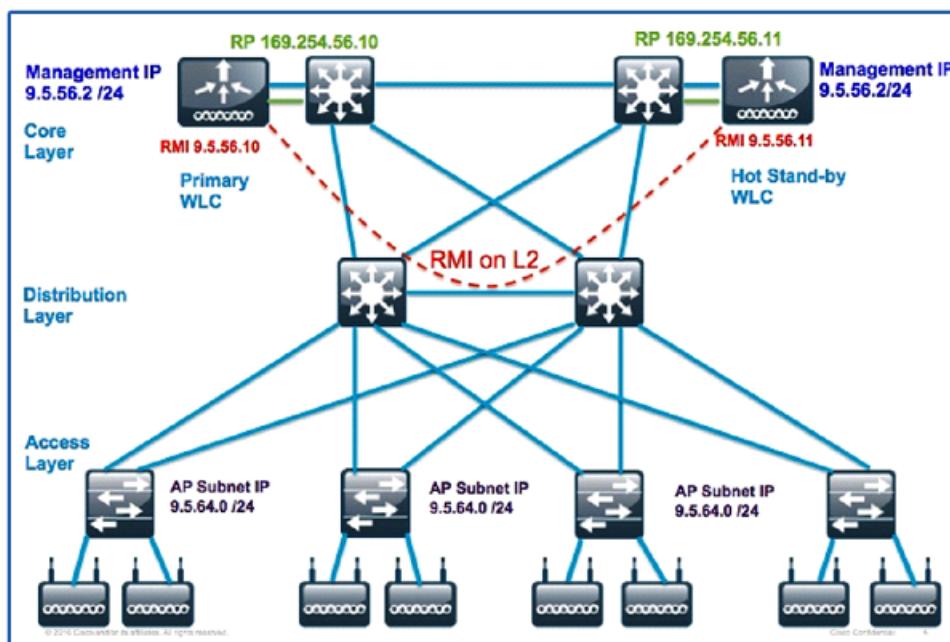

```
configure interface address management 9.5.56.3 255.255.255.0 9.5.56.1
```

```
configure interface address redundancy-management 9.5.56.11 peer-redundancy-management 9.5.56.10
```

```
configure redundancy unit secondary
```

```
configure redundancy mode sso
```

## RP Connectivity via Switches

**Figure 2 RP connectivity via switches**

- Redundancy Port connectivity via switches across data centers is supported in this topology.
- Configuration sync and Keepalives via Redundancy Port.
- RMI interface is created as part of Management subnet and is used to check peer and management gateway reachability.
- RTT Latency is 80 milliseconds by default. The RTT should be 80% of the Keepalive timer which is configurable in the range 100-400 milliseconds.
- Failure detection time is  $3 \times 100 + 60 + \text{jitter} (12 \text{ msec}) = \sim 400 \text{ msec}$

---

## Supported HA Topologies

- Bandwidth: 60 Mbps or more
- MTU: 1500

### **Configuration on Primary WLC**

```
configure interface address management 9.5.56.2 255.255.255.0 9.5.56.1

## Supported HA Topologies

350713

## VSS Configuration

Step	Command	Purpose
Step 1	Switch-1(config)# redundancy	Enters redundancy configuration mode.
Step 2	Switch-1(config-red)# mode sso	Configures SSO. When this command is entered, the redundant supervisor engine is reloaded and begins to work in SSO mode.
Step 3	Switch-1(config-red)# exit	Exits redundancy configuration mode.
Step 4	Switch-1(config)# routerouting_protocol processID	Enables routing, which places the router in router configuration mode.
Step 5	Switch-1(config-router)# nsf	Enables NSF operations for the routing protocol.
Step 6	Switch-1(config-router)# end	Exits to privileged EXEC mode.
Step 7	Switch-1# show running-config	Verifies that SSO and NSF are configured and enabled.
Step 8	Switch-1# show redundancy states	Displays the operating redundancy mode.

Step	Command	Purpose
Step 1	Switch-1(config)# switch virtual domain 100	Configures the virtual switch domain on Chassis A.
Step 2	Switch-1(config-vs-domain)# switch 1	Configures Chassis A as virtual switch number 1. For Chassis B config - Switch 2
Step 3	Switch-1(config-vs-domain)# exit	Exits config-vs-domain.

350714

Step	Command	Purpose
Step 1	Switch-1(config)# interface port-channel 10	Configures port channel 10 on Switch 1.
Step 2	Switch-1(config-if)# switch virtual link 1	Associates Switch 1 as owner of port channel 10.
Step 3	Switch-1(config-if)# no shutdown	Activates the port channel.
Step 4	Switch-1(config-if)# exit	Exits interface configuration mode.

Step	Command	Purpose
Step 1	Switch-2(config)# interface port-channel 20	Configures port channel 20 on Switch 2.
Step 2	Switch-2(config-if)# switch virtual link 2	Associates Switch 2 as owner of port channel 20.
Step 3	Switch-2(config-if)# no shutdown	Activates the port channel.
Step 4	Switch-2(config-if)# exit	Exits interface configuration mode.

350715

Step	Command	Purpose
Step 1	Switch-1# switch convert mode virtual	Converts Switch 1 to virtual switch mode. After you enter the command, you are prompted to confirm the action. Enter yes. The system creates a converted configuration file, and saves the file to the RP bootflash.

## Recommendations

- Round trip latency on Redundancy Link should be less than or equal to 80 milliseconds.
- Preferred MTU on Redundancy Link is 1500 or above.
- Bandwidth on Redundancy Link should be 60 Mbps or more.

## Supported HA Topologies

- If redundancy ports are connected via switches such that there is L2 adjacency between the two controllers, the RP VLAN should be excluded from the access VLAN configured on the switch for the management ports.
- For WiSM2 connectivity between two different chassis connected across the L2 network, the “redundancy-vlan” should be excluded from the access-VLAN configured on the switch for the management ports.
- It is important to use different sets of switches for the RP port connectivity and the management port traffic. Failure to do so results in an active-active scenario if the L2 switch reloads, causing the APs to lose connectivity, leading to downtime to clients.
- When deploying WiSM2 in VSS setup, it is recommended to set the peer search time to 180 seconds.

## AP And Client State Sync

- At this stage both the controllers are paired up in HA setup. Any configuration done on Active will be synced to Standby controller via redundant port. Check the WLAN summary and Interface summary on standby WLC from console connection.
- In High Availability setup, APs’ CAPWAP state is maintained on Active as well as Standby controller (only for APs which are in Run state) i.e. UP time and Associated UP time is synced from the active to the standby controller. In an example below WLC 1 is an Active state and serving the network and WLC 2 is in Standby state monitoring active controller. Although WLC 2 is in standby state it still maintains CAPWAP state of AP.

WLC 1->Console Connection:

```
(POD1-WLC) >show ap uptime

Number of APs..... 2
Global AP User Name..... Not Configured
Global AP Dot1x User Name..... Not Configured

AP Name          Ethernet MAC      AP Up Time        Association Up Time
-----          -----          -----          -----
POD1-AP1         6c:20:56:e1:50:09  0 days, 03 h 45 m 58 s  0 days, 00 h 24 m 11 s
POD1-AP2         44:d3:ca:42:31:57  0 days, 15 h 46 m 37 s  0 days, 00 h 24 m 07 s
```

350687

Observe the AP UP Time and Association UP Time on Active WLC

WLC 2->Console Connection:

```
(POD1-WLC-Standby) >show ap uptime

Number of APs..... 2
Global AP User Name..... Not Configured
Global AP Dot1x User Name..... Not Configured

AP Name          Ethernet MAC      AP Up Time        Association Up Time
-----          -----          -----          -----
POD1-AP1         6c:20:56:e1:50:09  0 days, 03 h 46 m 11 s  0 days, 00 h 24 m 24 s
POD1-AP2         44:d3:ca:42:31:57  0 days, 15 h 46 m 50 s  0 days, 00 h 24 m 20 s
```

350688

Observe the AP Uptime and Association UP Time on Standby WLC will be in sync with active WLC.

- In case of Box Failover i.e. Active controller crashes / system hang / manual reset / force switchover direct command is sent from Active controller via Redundant Port as well as from Redundant Management Interface to Standby controller to take over the network. Failover may take ~2-360 millisecond depending on number of APs/Clients on the active controller. In case of power failure on Active WLC or some crash where direct command for switchover cannot be sent to the standby

## Supported HA Topologies

controller, it may take ~360 – 990 msec depending upon number of APs/Clients on the active controller and the Keepalive timer configured. The default Keepalive timer is 100 milliseconds. Make sure that default RTT latency is less than or equal to 80 msec.

- With release 7.5 as part of Client SSO, the client database is also synced to standby WLC so Run state client entries will be present on Standby WLC.

WLC 1-> Console/Telnet/SSH Connection:

```
(POD1-WLC) >show client summary

RSN    70:de:e2:0e:ce:05  83725           0.0.0.0
-----+-----+-----+-----+-----+-----+
```

WLC 2:

## Supported HA Topologies

```
(POD1-WLC-Standby) >show pmk-cache all
Number of PMK Cache Entries: 2

PMK-CCKM Cache
-----  

Type     Station      Entry Lifetime   VLAN Override   IP Override   Audit-Session-ID  

-----  

RSN    28:e7:cF:ec:e9:58  89725          0.0.0.0  

RSN    70:de:e2:0e:ce:05  89725          0.0.0.0
```

350694

## Failover Process

- Issue a command **redundancy force-switchover** on Active controller. This command will trigger manual switchover where Active controller will reboot and Standby controller will take over the network. In this case Run state client on Active WLC will not be de-authenticated. The command **save config** is initiated before **redundancy force-switchover** command.

WLC 1-> Console Connection:

```
(POD1-WLC) >redundancy Force-switchover
Warning: Saving configuration change causes all the configurations to be saved on Flash.
If this is not what you intend to do, do not type 'y' below.

The system has unsaved changes.
Would you like to save them now? (y/N) y

Configuration Saved! Restarting system.
```

350695

WLC 2-> Console Connection:

```
(POD1-WLC-Standby) >
HA completed successfully, WLC switch over detection time : 2 msec and APs switch over time : 0 msec

(POD1-WLC) >show client detail 28:e7:cF:ec:e9:58
Client MAC Address..... 28:e7:cF:ec:e9:58
Client Username ..... H/A
AP MAC Address..... 64:d9:89:42:34:78
AP Name..... POD1-AP2
AP radio slot Id..... 1
Client State..... Associated
Client MAC DQB State..... Access
Wireless LAN Id..... 2
Hotspot (802.11u)..... Not Supported
BSSID..... 64:d9:89:42:34:78
Connected For ..... 284 secs
Channel..... 149
IP Address..... 10.10.11.76
Gateway Address..... 10.10.11.1
Netmask..... 255.255.255.0
IPv6 Address..... fe80::2ae7:ffff:feec:e958
Association Id..... 1
Authentication Algorithm..... Open System
Reason Code..... 1
Status Code..... 0
Session Timeout..... 1800
Client CCX version..... No CCX support
```

350696

Observe the change in prompt in above screen capture.

WLC 2->Console Connection:

## Supported HA Topologies

```
(POD1-WLC) >show ap uptime

Number of APs..... 2
Global AP User Name..... Not Configured
Global AP Dot1x User Name..... Not Configured

AP Name          Ethernet MAC          AP Up Time          Association Up Time
-----          -----          -----
POD1-AP1          6c:28:56:c1:58:09  0 days, 03 h 57 m 13 s  0 days, 00 h 35 m 26 s
POD1-AP2          44:d3:ca:42:31:57  0 days, 15 h 57 m 52 s  0 days, 00 h 35 m 22 s
```

250697

Observe the AP CAPWAP State on WLC 2 which was standby initially and is Active now after switchover. AP uptime as well as Association UP Time is maintained and AP did not go in discovery state.

2. Also notice client connectivity when switchover is initiated. Client will be not be de-authenticated.

Ping from wireless client to its gateway IP Address and management IP Address during switchover shows minimal loss.

၁၇၀

1

- ### **3. To check the redundancy status**

WLC 1 -> Console connection issue a command **show redundancy summary**:

## Supported HA Topologies

WLC 2 -> Console connection issue a command **show redundancy summary**:

```
(POD1-WLC) >show redundancy summary
  Redundancy Mode = SSO ENABLED
    Local State = ACTIVE ←
    Peer State = STANDBY HOT
      Unit = Secondary - HA SKU (Inherited AP License Count = 62)
        Unit ID = E0:2F:6D:5C:EE:A0
      Redundancy State = SSO (Both AP and Client SSO)
        Mobility MAC = E0:2F:6D:5C:F0:40

  Average Redundancy Peer Reachability Latency = 2660 usecs
  Average Management Gateway Reachability Latency = 751 usecs

  Redundancy Management IP Address..... 10.10.10.11
  Peer Redundancy Management IP Address..... 10.10.10.10
  Redundancy Port IP Address..... 172.16.10.11
  Peer Redundancy Port IP Address..... 172.16.10.10
  Peer Service Port IP Address..... 0.0.0.0

  Switchover History[1]:
  Previous Active = 10.10.10.10, Current Active = 10.10.10.11
  Switchover Reason = User initiated, Switchover Time = Wed Apr  3 02:01:21 2013
```

350700

WLC 2-> Click on Monitor > Redundancy > Summary:

350702

- Initiate a force switchover again on current active WLC.

WLC, which was configured as Primary Unit, should now be active and WLC, which was configured as Secondary Unit i.e., WLC 2 should be in Hot Standby State.

WLC 2:

## Supported HA Topologies

```
(POD1-WLC) >redundancy Force-switchover

Warning: Saving configuration change causes all the configurations to be saved on Flash.
If this is not what you intend to do, do not type 'y' below.

The system has unsaved changes.
Would you like to save them now? (y/N) y

Configuration Saved! Restarting system.
```

350703

WLC 1: Make sure Local state should be Active and Unit should be Primary on WLC 1 after switchover:

```
(POD1-WLC) >show redundancy summary
Redundancy Mode = SSO ENABLED
  Local State = ACTIVE
  Peer State = STANDBY HOT
  Unit = Primary
  Unit ID = E0:2F:60:5C:F0:40
  Redundancy State = SSO (Both AP and Client SSO)
  Mobility MAC = E0:2F:60:5C:F0:40
Management Gateway Failover = ENABLED (Management GW failover would be operational in few moments)
Link Encryption = DISABLED

  Redundancy Management IP Address..... 10.10.10.10
  Peer Redundancy Management IP Address..... 10.10.10.11
  Redundancy Port IP Address..... 169.254.10.10
  Peer Redundancy Port IP Address..... 169.254.10.11
  Peer Service Port IP Address..... 0.0.0.0
```

Observe the switchover history. WLC maintains 10 switchover histories with switchover reason.

```
Switchover History[1]:
Previous Active = 10.10.10.10, Current Active = 10.10.10.11
Switchover Reason = User initiated, Switchover Time = Wed Apr 3 02:01:21 2013
```

350705

## Client SSO Behavior and Limitations

- The Bonjour dynamic database comprising of the services and service providers associated with a service and the domain name database is synced to standby.
- Only clients that are in Run state are synced between the Active and Standby WLC. Client SSO does not support seamless transitions for clients that are in the process of associating/joining the controller. The clients in the transition phase will be de-authenticated after switchover and will need to rejoin the controller.
- Posture and NAC OOB are not supported if the client is not in Run state.
- With release 8.2.111.0 WGB and clients associated to the WGB will be state fully switched over with client SSO.
- CCX based applications need to be re-started post Switchover.
- New mobility is not supported.
- Client statistics are not synced.
- PMIPv6, NBAR, SIP static CAC tree are not synced, need to be re-learned after SSO.

---

High Availability in Release 8.0

- OEAP (600) clients are not supported.
- Passive clients need to be re-associated after SSO.
- Device and root certificates are not automatically synced to the Standby controller.
- AP and Client Rogue information is not synced to the Standby controller and needs to be re-learnt when the hot standby becomes the active controller.
- Sleeping client information is not synced to the standby controller.
- NBAR statistics are not synced to the secondary controller.
- Native Profiling data is not synced to the secondary controller, therefore, clients will be re-profiled after switchover.
- The below table captures the behavior w.r.t SSO with MAPs and RAPs.

	AP SSO	Client SSO
RAP	Supported	Not supported
MAP	Not Supported	Not supported

## High Availability in Release 8.0

High Availability in release 8.0 introduces enhancements and improvements to the High Availability feature-set. The following enhancements are captured in this section:

- Bulk sync status
- Enhanced debugs and serviceability for HA
- Configurable keep-alive timer/retries and peer-search timer value
- Peer RMI ICMP ping replaced with UDP messages
- Standby WLC on-the-fly maintenance mode
- Default gateway reachability check enhancement
- Faster HA Pair up

High Availability in release 8.0 also introduces new features enabling SSO such as:

- Internal DHCP server support for SSO enabled controllers
- AP radio CAC statistics sync
- SSO support for sleeping client feature
- SSO support for OEAP 600 APs

**Note:** Release 8.0 onwards, it is mandatory to tag the RMI and management interfaces to avoid false switchovers.

## Enhancements and Improvements

### Bulk Sync Status

Currently, the controller does not provide any indication for the completion of Bulk Sync configuration once it is initiated. The Bulk Sync can be verified only by user observation and by manually checking the number of clients synced to the standby WLC. As part of this feature, a mechanism is provided to convey the status of Bulk Sync (both AP and client sync) when standby WLC comes up.

A new field called **BulkSync Status** is added in the GUI under **Controller > Redundancy > Summary**. This field points to the status of the bulk sync to the standby WLC and the status can be Pending/In-progress/Complete.

**Figure 9 BulkSync Status GUI**

CISCO		MONITOR	WLANs	CONTROLLER	WIRELESS
Monitor	Redundancy Summary				
Summary	Local State	ACTIVE			
Access Points	Peer State	STANDBY HOT			
Cisco CleanAir	Unit	Primary			
Statistics	Unit Id	6C:20:56:64:B9:A0			
CDP	Redundancy State	SSO			
Rogues	Maintenance Mode	Disabled			
Redundancy	Maintenance Cause	Disabled			
Statistics	Average Redundancy Peer Reachability Latency (usecs)	450			
Summary	Average Management Gateway Reachability Latency(usecs)	2094			
Detail					
Clients	BulkSync Status	Complete			
Sleeping Clients					
Multicast					
Applications					
Local Profiling					

The output of the CLI command `show redundancy summary` also displays the Bulk Sync status, which can be Pending/In-progress/Complete as shown below while pairing with the standby controller.

When the standby controller is booting up, the **BulkSync** status shows **Pending**.

**Figure 10 BulkSync Status—Pending**

```
(Cisco Controller) >show redundancy summary
  Redundancy Mode = SSO ENABLED
    Local State = ACTIVE
    Peer State = UNKNOWN - Communication Down
      Unit = Primary
      Unit ID = 6C:20:56:64:B9:A0
  Redundancy State = Non Redundant
    Mobility MAC = 6C:20:56:64:B9:A0
  BulkSync Status = Pending
```

362777

Once the standby controller completes the boot-up process and the bulk sync starts, the status changes to **In-Progress**.

**Figure 11 BulkSync Status—In-Progress**

```
(Cisco Controller) >
Blocked: Configurations blocked as standby WLC is still booting up.
          You will be notified once configurations are Unblocked

Unblocked: Configurations are allowed now...

(Cisco Controller) >show redundancy summary
  Redundancy Mode = SSO ENABLED
    Local State = ACTIVE
    Peer State = STANDBY HOT
      Unit = Primary
      Unit ID = 6C:20:56:64:B9:A0
  Redundancy State = SSO
    Mobility MAC = 6C:20:56:64:B9:A0
  BulkSync Status = In-Progress

Average Redundancy Peer Reachability Latency = 0 usecs
Average Management Gateway Reachability Latency = 5802 usecs
```

When the bulk sync process is complete, the **BulkSync** status changes to **Complete**.

**Figure 12 BulkSync Status—Complete**

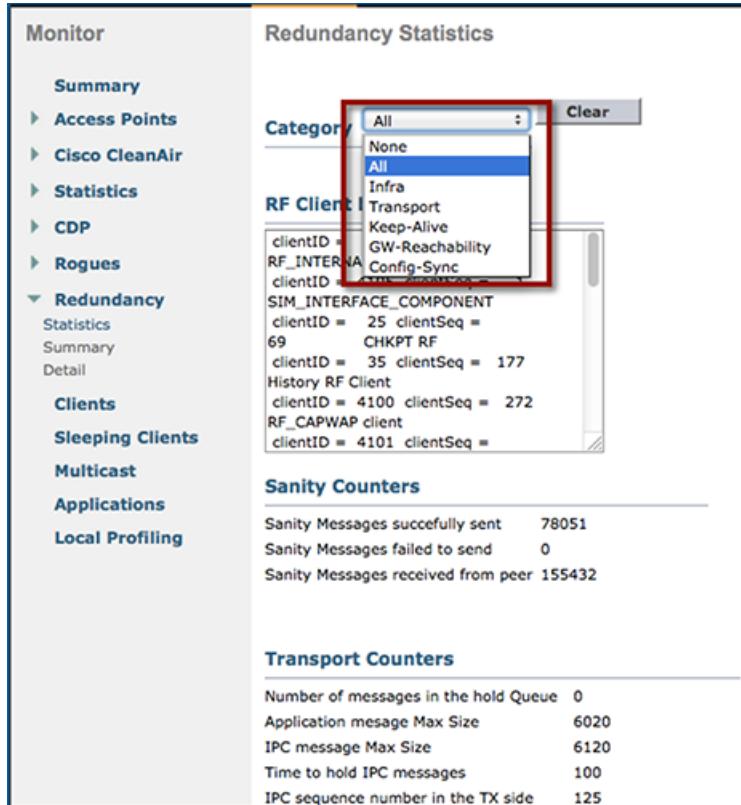

```
(Cisco Controller) >show redundancy summary
    Redundancy Mode = SSO ENABLED
        Local State = ACTIVE
        Peer State = STANDBY HOT
            Unit = Primary
                Unit ID = 6C:20:56:64:B9:A0
    Redundancy State = SSO
        Mobility MAC = 6C:20:56:64:B9:A0
    BulkSync Status = Complete
Average Redundancy Peer Reachability Latency = 459 usecs
Average Management Gateway Reachability Latency = 4520 usecs
```

## Debug>Show Command Enhancements

As HA plays a major role in avoiding network outage, it should also be pertinent to be able to debug the state changes on the boxes at the time of SSO or at a later point in time.

The following new categories of statistics are introduced under **Monitor > Redundancy > Statistics**:

- a. All
- b. Infra
- c. Transport
- d. Keep-Alive
- e. GW-Reachability
- f. Config-Sync

**Figure 13 Redundancy Statistics GUI**

The Infra statistics contain RF Client details and Sanity Counters as shown in [Figure 14 on page 57](#).

**Figure 14 Redundancy Statistics–Infra**

The screenshot shows the Cisco Monitor interface with the 'MONITOR' tab selected. The left sidebar under 'Monitor' has a 'Redundancy' section expanded, with 'Statistics' selected. The main content area is titled 'Redundancy Statistics' and shows a 'Category' dropdown set to 'Infra' with a red arrow pointing to it. Below the dropdown is a section titled 'RF Client brief' containing client ID and sequence number pairs. Further down is a 'Sanity Counters' section with message counts.

**Category:** Infra

**RF Client brief**

clientID = 0	clientSeq = 0
RF_INTERNAL_MSG	
clientID = 4105	clientSeq = 1
SIM_INTERFACE_COMPONENT	
clientID = 25	clientSeq =
69	CHKPT RF
clientID = 35	clientSeq = 177
History RF Client	
clientID = 4100	clientSeq = 272
RF_CAPWAP client	
clientID = 4101	clientSeq =

**Sanity Counters**

Sanity Messages successfully sent	78108
Sanity Messages failed to send	0
Sanity Messages received from peer	155546

**Figure 15 Redundancy Statistics –Transport**

The screenshot shows the Cisco Monitor interface with the 'MONITOR' tab selected. On the left, a sidebar under 'Monitor' includes 'Summary', 'Access Points', 'Cisco CleanAir', 'Statistics', 'CDP', 'Rogues', and a expanded 'Redundancy' section with 'Statistics', 'Summary', and 'Detail'. The main content area is titled 'Redundancy Statistics' and shows a 'Category' dropdown set to 'Transport' with a red arrow pointing to it. Below this is a table titled 'Transport Counters' with the following data:

Number of messages in the hold Queue	0
Application message Max Size	6020
IPC message Max Size	6120
Time to hold IPC messages	100
IPC sequence number in the TX side	131
IPC sequence number in the RX side	0
IPC sequence number mismatches(Low)	0
IPC sequence number mismatches(high)	0

The Heartbeat debugs include events of reception of heartbeats, loss of heartbeats, and subsequent actions related to them.

**Figure 16 Redundancy Keep-alive Statistics**

The screenshot shows the Cisco Monitor interface with the 'MONITOR' tab selected. On the left, the 'Monitor' menu is open, showing various options like 'Summary', 'Access Points', 'Cisco CleanAir', 'Statistics', 'CDP', 'Rogues', 'Redundancy', 'Clients', 'Sleeping Clients', 'Multicast', 'Applications', and 'Local Profiling'. Under 'Redundancy', there are three sub-options: 'Statistics', 'Summary', and 'Detail'. The main content area is titled 'Redundancy Statistics'. A dropdown menu labeled 'Category' is open, with 'Keep-Alive' selected. A red arrow points to this dropdown. Below it, the 'Keepalive Counters' table is displayed:

Event	Count
Keep Alive Request Received	772
Keep Alive Request Received	78
Keep Alive Request Sent	78
Keep Alive Response Sent	772
Keep Alive Requests failed to send	0
Keep Alive Responses to failed to send	0
Number of times two Keepalives are lost consecutively	0

Below this is a section titled 'Network Latencies (RTT) for the Peer Reachability in microsec' with a table:

Peer Reachability	Latency (usecs)
1	526
2	813
3	777
4	466
5	465
6	467
7	463
8	467
9	474
10	484

The HA system monitors management gateway reachability to reduce network outage.

On the Standby controller, serviceability debugs related to the gateway reachability of the active controller and standby controller, their health states, and actions taken based on this information is reported. While on the active controller, the reachability of active WLC to the gateway alone is reported.

## High Availability in Release 8.0

**Figure 17 Redundancy GW-Reachability Statistics**

**Redundancy Statistics**

**Gw Reachability Counters**

Gw Pings Successfully sent	785
Gw Pings Failed to send	0
Gw Responses Received	785
Current consecutive Gw Responses Lost	0

- 13. show redundancy config-sync statistics**
- 14. show redundancy ap-sync statistics**
- 15. show redundancy client-sync statistics**

## Configurable Keep-alive and Peer-Search Parameters

To address the variable network latencies in different customer deployment scenarios, keep-alive and peer-search parameters are made configurable. As part of this enhancement, the maximum number of Keepalives between active and standby controllers to trigger a failover is now configurable. Also, peer-search timer and keep-alive timer are modified to support an extended range.

The following new CLI command is added to configure the number of redundancy keep-alive retries in the range of 3 to 10.

**Figure 19 Redundancy retries CLI Command**

```
(Cisco Controller) >config redundancy retries ?
keep-alive-retry Configure the keep-alive retry count between 3 and 10
gateway-retry Configure the gateway retry count values between 6 to 12
(Cisco Controller) >config redundancy retries keep-alive-retry ? ←
<retry count> Configures keep-alive retry count between 3 and 10
9/27/95
```

The existing CLI command `config redundancy timer keep-alive-timer` of keep-alive timer is modified to support keep-alive timer from 100 to 1000 msecs.

The existing CLI command `config redundancy timer peer-search-timer` of peer-search timer is modified to support peer-search timer from 60 to 300 secs.

**Figure 20 Redundancy timer CLI Command**

```
(Cisco Controller) >config redundancy timer ?  
keep-alive-timer Configure the keep-alive timer in milli seconds between 100 and  
1000 in multiple of 50. ←  
peer-search-timer Configure the peer search timer in seconds between 60 and 300.  
← 352788
```

The following CLI is introduced to view the redundancy keep-alive-retry value.

**Figure 21 Show redundancy retries CLI Command**

```
(Cisco Controller) >show redundancy retries keep-alive-retry  
Keep Alive Retries : 4  
← 352788
```

Use the `show redundancy timers` command to view the peer-search-timer and keep-alive-timer values.

**Figure 22 Show redundancy timers CLI Command**

```
(Cisco Controller) >show redundancy timers peer-search-timer  
Peer Search Timer : 300 secs ←  
  
(Cisco Controller) >show redundancy timers keep-alive-timer  
Keep Alive Timer : 500 nsecs ←  
← 352788
```

Use the `show redundancy detail` command to display the keep-alive and peer-search timeout values.

**Figure 23** Show redundancy detail CLI Command

```
(Cisco Controller) >show redundancy detail ?

(Cisco Controller) >show redundancy detail
Redundancy Management IP Address..... 9.5.56.10
Peer Redundancy Management IP Address..... 9.5.56.11
Redundancy Port IP Address..... 169.254.56.10
Peer Redundancy Port IP Address..... 169.254.56.11
Peer Service Port IP Address..... 0.0.0.0

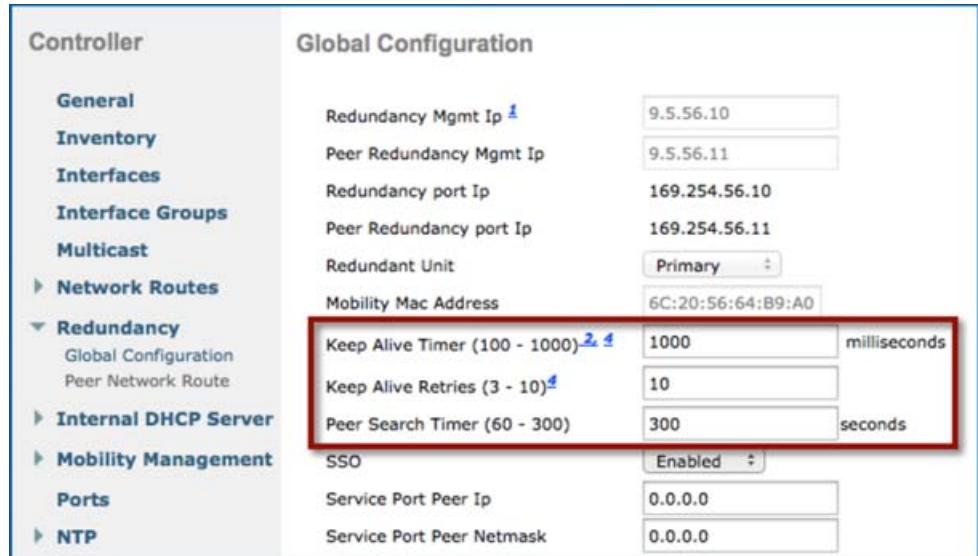

Redundancy Timeout Values.....
-----
Keep Alive Timeout : 500 msecs
Peer Search Timeout : 300 secs

Number of Routes..... 0

-----      -----      -----
(Cisco Controller) >
```

352790

The keep-alive timer, keep-alive retries, and peer-search timer can also be configured and viewed from the **Controller > Redundancy > Global Configuration** page in the GUI.

**Figure 24** Redundancy Global Configuration GUI

### Peer RMI ICMP Ping Replaced with UDP Messages

Prior to release 8.0, ICMP ping is used to heart-beat with the peer WLC over the Redundancy Management Interface. As part of this feature for release 8.0, ICMP ping is replaced with a UDP message.

This will benefit due to the following factors:

- ICMP ping packets might get discarded under heavy loads.

- Any other device with the same IP might also reply to the ping.

It is recommended to tag the RMI and management interfaces to avoid false Switchovers. Tagging of the RMI and management interfaces is now mandatory in release 8.0 to pair WLCs in SSO mode.

## Standby WLC On-the-Fly Maintenance Mode (MTC)

Prior to release 8.0 when the standby controller loses reachability to the “Default Gateway” or “Peer RP”, the controller reboots and checks that condition while booting up and enters into the MTC mode. With this feature, the standby WLC will enter into the MTC mode “on-the-fly” without rebooting when such error scenarios occur. Once Peer-RP and the default gateway reachability is restored, the MTC mode auto-recovery mechanism introduced in release 7.6, will reboot the WLC and pair it with the active WLC. This mechanism is applicable only to the standby WLC. The active controller will still reboot before going to MTC mode.

## Default Gateway Reachability Check Enhancement

As part of this enhancement, the gateway (GW) reachability check mechanism is modified to avoid false positives and it is also modified for the ideal time to start checking for gateway reachability once the controller boots up.

Prior to release 8.0, the “GW reachability check” is performed during Role negotiation. In release 8.0 and later, during Role negotiation, GW reachability check is not performed and is initiated only after the HA Pair-Up is complete.

Also, it is observed that certain Switch/Router configurations rate limits ICMP ping packets or drop them altogether. To avoid such conditions triggering false-positives, the new design ensures not to take switchover decisions purely based on ICMP ping losses. By the modified logic, upon 6 consecutive ping drops, an ARP request is sent to the GW IP address. A successful response to this request is considered as the GW being reachable.

## Faster HA Pair Up

Currently during the HA pairing process, once the active-standby role is determined, the configuration is synced from the active WLC to the standby WLC via the Redundancy Port. If the configuration is different, the secondary WLC reports XML mismatch and downloads the configuration from the active controller and reboots again. In the next reboot after role determination, it validates the configuration again, reports no XML mismatch, and proceeds further in order to establish itself as the Standby WLC.

With this feature enhancement, the XMLs are sent from the **to-be-Active** to **to-be-Standby** controller at the time of initialization, just before the validation of the XMLs. This avoids the extra step of comparison and reboot since no other modules are initialized yet, resulting in faster pair up of Active and Standby WLCs.

As seen in the boot logs below, there are no comparison of XMLs and no reboot of standby WLC.

**Figure 25** Standby WLC bootup log

## New Features Support in SSO

### SSO Support for Internal DHCP Server

Prior to release 8.0, configuration of “Internal DHCP Server” is not allowed on HA enabled controllers because the internal DHCP server data is not synced to the standby WLC. In release 8.0 and later, “Internal DHCP Server” is configured on HA enabled controllers and this data is synced to the standby WLC so that soon after a switchover, the “Internal DHCP Server” on the new active controller starts serving clients.

To configure the Internal DHCP server using the GUI, navigate to **Controller > Internal DHCP Server**

**Figure 26** Internal DHCP Server GUI

The same is synced to the standby controller and is verified by executing the CLI command `show dhcp summary`

**Figure 27** show dhcp summary on Active and Standby WLC

```
(Cisco Controller) >show dhcp summary
Scope Name           Enabled      Address Range
DHCPScope           Yes         11.11.11.0 -> 11.11.11.255 ←

-----
(Cisco Controller-Standby) >show dhcp summary
Scope Name           Enabled      Address Range
DHCPScope           Yes         11.11.11.0 -> 11.11.11.255 ←
```

## AP Radio CAC Statistics Sync

As part of this enhancement, Static CAC method bandwidth allocation parameters for Voice and Video and Call Statistics are synced to the Standby WLC, so that soon after a switchover, respective information is available on the new active controller that will be used for call admission control.

## SSO Support for Sleeping Clients

Release 7.5 did not provide SSO support for sleeping clients. The sleeping client database was not synced to the standby controller, which caused the sleeping clients to re-authenticate after a switchover occurred. With this release, sleeping client database is synced to the standby controller, allowing sleeping clients to avoid web re-authentication if they wake up within the sleeping client timeout interval.

The CLI command `show custom-web sleep-client summary` is used to verify the sleeping client database sync between the active and standby WLC.

**Figure 28** Sleeping Client Database on Primary WLC

```
(Cisco Controller) >show custom-web sleep-client summary

Active Sleep-Client entries.....1
Max Sleep-Client entries supported....1000

MAC Address of Client      UserName      Time Remaining

352797
```

## SSO Support for OEAP 600 APs

Prior to release 8.0, when a switchover occurs on an HA pair, OEAP 600 APs restarts the CAPWAP tunnel and joins back the new active controller, and all the connected clients are de-authenticated. As a part of this feature, OEAP 600 APs ensure not to reset their CAPWAP tunnel. Also, clients continue their connection with the new active controller in a seamless manner.

As shown below, the output of `show ap summary` and `show client summary` command on the active and standby controllers displays the AP and client database sync.

## High Availability in Release 8.1

## High Availability in Release 8.1

High Availability in release 8.1 introduces the HA Standby monitoring feature.

## High Availability in Release 8.1

## HA Standby Monitoring Feature Introduction

From the client's perspective, although the Active and Hot Standby controllers constitute a single entity, from the administrator's perspective, they are still considered, maintained, and monitored as two separate controllers. The administrator fetches the status and health information of Active and Standby WLCs separately to monitor and maintain the controllers on a continuous basis with the help of management infrastructure and various user interfaces.

This section outlines the interfaces to fetch the health state information and traps from the Standby controllers and also describes how to use these user interfaces through the CLI, GUI, and SNMP.

## Events and Notifications

### Trap When WLC Turns Hot Standby

A trap is reported with time stamp when HA peer becomes Hot-Standby, and the following trap is reported:

RF notification EventType:37 Reason: HA peer is Hot-Standby...At:Wed Oct 29 18:53:01 2014  
A new trap type is added in CISCO-LWAPP-HA-MIB.my.

## Trap when Standby WLC goes Down

When the standby peer goes down due to any of the following events,

- Manual Reset
- Crash
- Memory Leak/Hang
- Moving to maintenance mode

the below trap is reported:

RF failure notification ErrorType: 34 Reason :Lost Peer, Moving to Active-No-Peer State!  
A new trap type is added in CISCO-RF-SUPPLEMENTAL-MIB.my.

## Syslog notification when Admin login on Standby

## Admin Login to Standby Using SSH

This generates an event in msglog / syslog and message snippet is as follows:

```
*emWeb: Oct 06 20:34:42.675: #CLI-3-LOGIN_STANDBY: [ss] cli_lv17.c:4520 [USER@9 name="admin" from="SSH"] user login success on standby controller.
```

This message can be viewed on the Standby WLC by executing the CLI '**show msglog**'

## High Availability in Release 8.1

```
(Cisco Controller-Standby) >show msglog
Message Log Severity Level ..... VERBOSE
*emWeb: Oct 06 20:34:42.675: #CLI-3-LOGIN_STANDBY: [SS] cli_lv17.c:4520 [USER@9 name="admin" from="SSH"] user
login success on standby controller.
```

**Admin Login to Standby Using Console**

This generates an event in msglog/syslog and message snippet is as follows:

```
*emWeb: Oct 06 20:34:42.675: #CLI-3-LOGIN_STANDBY: [SS] cli_lv17.c:4520 [USER@9 name="admin" from="console"]
user login success on standby controller.
```

This message can be viewed on the Standby WLC by executing the CLI '**show msglog**'

```
(Cisco Controller-Standby)

Enter User Name (or 'Recover-Config' this one-time only to reset configuration to factory defaults)

User: admin
Password:*****
User login success on standby
Your password does not meet the strong password requirements. For added security, set a new password that
meets these requirements. To prevent this message from showing again, disable the strong password feature.
(Cisco Controller-Standby) >
(Cisco Controller-Standby) >show msglog
Message Log Severity Level ..... VERBOSE
*emWeb: Oct 06 20:34:42.675: #CLI-3-LOGIN_STANDBY: [SS] cli_lv17.c:4520 [USER@9 name="admin" from="console"]
user login success on standby controller.
```

**Peer Process Statistics on CLI**

As part of this feature, CPU and Memory statistics of all the threads of the Standby WLC are synced to Active controller every 10 seconds. This information is displayed when the user queries for the Peer statistics on the active WLC.

New Commands on Active WLC to display peer process System, CPU and memory statistics are as follows:

- **show redundancy peer-system statistics**
- **show redundancy peer-process cpu**
- **show redundancy peer-process memory**

```
(Cisco Controller) >show redundancy peer-system statistics
Peer System CPU statistics:Current CPU(s) load: 0%
Individual CPU load: 0%/1%, 0%/0%, 0%/0%, 0%/0%, 0%/0%, 0%/0%, 0%/0%, 0%/0%, 0%/0%
Peer System Memory Statistics:
Total System Memory.....: 1025646592 bytes (978.20 MB)
Used System Memory.....: 544792576 bytes (519.59 MB)
Free System Memory.....: 480854016 bytes (458.61 MB)
Bytes allocated from RTOS.....: 89576252 bytes (85.43 MB)
Chunks Free.....: 316 bytes
Number of mmaped regions.....: 48
Total space in mmaped regions.: 293515264 bytes (279.93 MB)
Total allocated space.....: 28793316 bytes (27.46 MB)
Total non-inuse space.....: 60782936 bytes (57.97 MB)
Top-most releasable space.....: 810440 bytes (791.44 KB)
Total allocated (incl mmap)....: 383091516 bytes (365.37 MB)
Total used (incl mmap).....: 322308580 bytes (307.39 MB)
Total free (incl mmap).....: 60782936 bytes (57.97 MB)
Peer system Power supply statistics:
Power Supply 1..... Present, OK
Power Supply 2..... Absent
```

## Peer Process Statistics on GUI

Peer statistics on the GUI can be viewed under **Monitor > Redundancy > Peer Statistics**.

**Figure 35 Peer Process System Statistics**

MIB CISCO-LWAPP-HA-MIB.my is updated to capture these statistics.

## HA Monitoring Enhancements in release 8.7

**Figure 36 Peer Process CPU Statistics**

The screenshot shows the Cisco Controller's monitoring interface. The top navigation bar includes tabs for MONITOR, WLANS, CONTROLLER, WIRELESS, SECURITY, and MANAGEMENT. The MONITOR tab is selected. Below the navigation bar, the left sidebar lists various monitoring categories: Summary, Access Points, Cisco CleanAir, Statistics, CDP, Rogues, Redundancy (with 'Peer Statistics' highlighted by a red arrow), Statistics, Summary, Detail, Clients, Sleeping Clients, Multicast, Applications, Lync, and Local Profiling. The main content area is titled 'Peer Process CPU Statistics' and displays a table of tasks and their CPU usage. The table has columns for Name, PID, Priority, CPU Use, (usr/sys)% hwm, CPU, and Reaper. The tasks listed include System Reset Task, reaperWatcher, osapiReaper, TempStatus, rsyncmgrSndqTask, rsyncmgrHoldqTask, rsyncmgrRvqTask, pktDebugSocketTask, webauthRedirect, emWeb, mdnsHATask, Bonjour\_Socket\_Task, Bonjour\_Process\_Tas, Bonjour\_Msg\_Task, Tunnel cleanup Task, portalSockTask, portalMsgTask, portalMonitorMsgTask, Tunnel Process Task, IWAG GTP PDP direct, IWAG GTP Audit Mang, PMIPv6\_Thread\_3, PMIPv6\_Thread\_2, PMIPv6\_Thread\_1, PMIPv6\_Thread\_0, hotspotTask, HAConfigSyncTask, ipv6SocketTask, IPv6\_Msg\_Task, and sidfSwitcherTask.

Name	PID	Priority	CPU Use	(usr/sys)% hwm	CPU	Reaper

**Figure 37 Peer Process Memory Statistics**

## HA Monitoring Enhancements in release 8.7

For Management - SNMP MIB is part of - MIB CISCO-LWAPP-HA-MIB.my is updated to capture the statistics discussed below.

By going to Monitor TAB on the controller and then choosing Redundancy, you can Monitor Statistics.

## HA Monitoring Enhancements in release 8.7

The screenshot shows the Cisco Monitor interface with the following details:

- Top Navigation:** MONITOR, WLANs, CONTROLLER, WIRELESS, SECURITY, MANAGEMENT.
- Left Sidebar:** Monitor, Summary, Access Points, Cisco CleanAir, Statistics, CDP, Rogues, Redundancy (expanded), Statistics, Peer Statistics (highlighted with a red arrow), Summary, Detail, Clients, Sleeping Clients, Multicast, Applications, Lync, Local Profiling.
- Selected Tab:** Peer Statistics (highlighted with a red arrow).
- Sub-Tab:** Statistics (highlighted with a red box).
- Content Area:** Peer Process Memory Statistics table.

Name	Priority	BytesInUse	BlocksInUse	Reaper
System Reset Task (240/ 7)	0	0	( 0/ 0)%

## Web Links

The screenshot shows the Cisco Prime NCS interface. The top navigation bar includes MONITOR, WLANS, CONTROLLER, WIRELESS, SECURITY, and MANAGEMENT. The MONITOR tab is selected. The left sidebar under the Monitor tab lists various monitoring categories: Summary, Access Points, Cisco CleanAir, Statistics, CDP, Rogues, Redundancy, and Applications. The 'Redundancy' section is expanded, and its 'Statistics' link is highlighted with a red box. Below this, 'Peer Statistics' is also highlighted with a red box. The main content area displays 'Peer System Statistics' with sections for Current CPU(s) load (0%) and Individual CPU Usage (0%/1%, 0%/1%, 0%/1%, 0%/1%). A large box highlights the 'Peer System Memory Statistics' section, which provides detailed memory usage metrics. At the bottom of the page, a status bar shows 'Serial Number FOC2115Q01X' and 'Fan Status OK', with a red arrow pointing to the 'Serial Number' field.

## Terminology

- APM—AP Manager Interface
- Dyn—Dynamic Interface
- Management—Management Interface
- Port—Physical Gbps port
- WiSM-2—Wireless Service Module
- AP—Access Point
- LAG—Link Aggregation
- SPAN—Switch Port Analyzer
- RSPAN—Remote SPAN
- VACL—VLAN Access Control List
- DEC—Distributed Etherchannel
- DFC—Distributed Forwarding Card
- OIR—Online Insertion and Removal
- VSL—Virtual Switch Link
- ISSU—In Service Software Upgrade
- MEC—Multichassis Ether Channel
- VSS—Virtual Switch System
- WCS—Wireless Control System
- NAM—Network Analysis Module
- IDSM—Intrusion Detection Service Module
- FWSM—Firewall Service Module
- STP—Spanning Tree Protocol
- VLAN—Virtual LAN
- SSO—Stateful Switchover
- WCP—Wireless Control Protocol
- WiSM-2—Wireless Service Module-2

# Glossary

## A

**AP SSO** Access Point State Full Switchover where CAPWAP state for each AP is maintained on Active and Standby WLC and CAPWAP state is retained after switchover to Standby WLC. AP need not go through CAPWAP discovery and join process after failover.

**Active WLC** This is the WLC which is currently active in HA pair and taking care of the wireless network. APs establish single CAPWAP tunnel with Active WLC.

## C

**Client SSO** Wireless Client State Full Switchover where client state is also maintained on Active and Standby WLC and wireless clients are not de-authenticated after switchover. Will be supported in future release.

## K

**Keep-Alive-Timer** Standby WLC in HA setup sends keep-alive packets on redundancy port to check the health of active WLC. With no acknowledgment of three keep-alive packets from active WLC, standby declares active as dead and takes over the network.

## M

**Maintenance Mode** When Standby WLC cannot communicate to gateway or cannot discover peer WLC i.e. active WLC via redundant port it goes in Maintenance mode. In this mode WLC cannot communicate to infra network and will not participate in HA process. Because WLC in maintenance mode does not participate in HA process it need to be manually rebooted to bring it out of maintenance mode and make participate in HA process again.

**Mobility MAC** Unique MAC address shared between peers in HA setup. This mac address should be used to form a mobility pair between HA setup and another WLCs in HA setup or with independent controllers. By default active WLC mac address is shared as mobility mac address but mobility mac can also be manually configured on active WLC using a CLI, which will be shared between peers in HA setup.

## P

**Peer** AP SSO is box-to-box redundancy i.e. 1:1 so both the WLCs (Active and Standby) in HA setup are peer to each other.

**Primary Unit** In AP SSO deployment controller running higher permanent count licenses should be configured as primary unit. Primary Unit is the WLC, which will take the role of Active WLC first time it forms HA pair. Primary Unit sends the lic count information to its peer via redundant port.

**Peer-Search-Timer** While booting, standby WLC waits for peer search timer (default 2 minutes) to discover the peer. If WLC cannot discover its peer within this time it will transition its state to maintenance mode.

## R

**Redundancy Port** Physical Port on 5500/7500/8500 WLC for HA role negotiation, configuration sync and redundancy messages between Active and Standby WLC.

**Redundancy Vlan** Vlan created on Cat6500 Sup for WiSM-2 Redundancy Port that is connected to Cat6k backplane to exchange configuration and redundancy messages including HA role negotiation between Active and Standby WLC.

---

## Glossary

<b>Redundancy Management Interface</b>	A parallel interface to management interface on both the WLC in HA setup. Should be in same subnet as management interface. This interface let standby WLC interact with infra network and also exchange some redundancy messages over infra network between Active and Standby WLC.
<b>S</b>	
<b>Standby WLC</b>	This is the WLC that is monitoring active controller in HA pair and ready to take over the wireless network in event of Active WLC failure.
<b>Secondary Unit</b>	In AP SSO deployment controller running lower or equal permanent count lic should be configured as secondary unit OR controller with HA SKU UDI (zero AP count lic) is shipped default as secondary unit. Secondary Unit is the WLC, which will take the role of Standby WLC first time it forms HA pair. Secondary unit inherit the lic count information from its peer i.e. Active WLC via redundant port.
